JONES & BARTLETT
LEARNING

World Headquarters
Jones & Bartlett Learning
5 Wall Street
Burlington, MA 01803
978-443-5000
info@jblearning.com
www.jblearning.com

Jones & Bartlett Learning books and products are available through most bookstores and online booksellers. To contact Jones & Bartlett Learning directly, call 800-832-0034, fax 978-443-8000, or visit our website, www.jblearning.com.

Substantial discounts on bulk quantities of Jones & Bartlett Learning publications are available to corporations, professional associations, and other qualified organizations. For details and specific discount information, contact the special sales department at Jones & Bartlett Learning via the above contact information or send an email to specialsales@jblearning.com.

CONTENTS

SECTION I Foundations & Safety

CHAPTER 1 Introduction to MORE

Applications	4
Introduction	5
Skills and Responsibilities of MORE Technicians	5
Pre-start Safety Inspection	6
What Is Mobile Off-Road Heavy Equipment?	7
Development Milestones of Off-Road Mobile Equipment	10
Off-Road Machine Design	16
What Does a Heavy Equipment Repair Technician Do?	21
Ready for Review	23
Key Terms	23
Review Questions	24
ASE Technician A/Technician B Style Questions	24

CHAPTER 2 Identification & Classifications of MORE 26

Introduction	27
Basic Categories of MORE	27
MORE Construction Features	36
MORE Terminology	39
Industry/Accreditation	40
MORE Attachments	40
MORE Systems and Components	43
Attitude	44
Ready for Review	45
Key Terms	46
Review Questions	46
ASE Technician A/Technician B Style Questions	47

CHAPTER 3 Shop and Machine Safety 49

Introduction	50
Identification of Workplace Hazards	52
Hazard Assessment and Control Procedures	66
Safety Regulations, Procedures, and Occupational Safety Standards	68
Emergency Actions and Procedures	69
Selection and Use of Personal Protective Equipment (PPE)	75
Safe MORE Service and Repair	81
Ready for Review	82

Key Terms	83
Review Questions	84
ASE Technician A/Technician B Style Questions	85

CHAPTER 4 Bearings, Seals, Lubricants, Gaskets, and Sealants 87

Introduction	88
Purpose, Operation, and Construction of Seals and Bearings	88
Bearing and Seal Servicing	96
Adjusting Bearing Preload	106
Removal, Installation, and Replacement of Seals	107
Causes of Seal and Bearing Failures	109
Gasket Servicing	110
Types and Applications of Sealants	110
Fluids and Lubricants	111
Ready for Review	116
Key Terms	117
Review Questions	118
ASE Technician A/Technician B Style Questions	119

CHAPTER 5 Tools and Fasteners 120

Introduction	121
Purpose and Usage of Tools	121
Tools and Equipment Fundamentals	122
Purpose, Usage, and Types of Fasteners	142
Ready for Review	153
Key Terms	153
Review Questions	156
ASE Technician A/Technician B Style Questions	156

CHAPTER 6 Oxyacetylene-Heating and Cutting Equipment 158

Introduction	159
Oxyacetylene Equipment and Components	159
Safety Regulations	163
Oxyacetylene Heating, Cutting, and Welding	165
Oxyacetylene Brazing and Soldering	168
Oxyacetylene Welding Repair Techniques	171
Industry/Accreditation	173
Attitude	173
Ready for Review	174
Key Terms	175

Review Questions	175
ASE Technician A/Technician B Style Questions . . .	176

CHAPTER 7 Shielded Metal Arc, MIG, and TIG Welding 178

Introduction	179
Shielded Metal Arc Welding (SMAW) Equipment and Components	179
Safety Regulations	183
Shielded Metal Arc Welding of Mild Steel	186
Air-Arc Gouging	190
Attitude	191
SMAW Terminology	192
SMAW Repair Techniques	192
Ready for Review	193
Key Terms	194
Review Questions	194
ASE Technician A/Technician B Style Questions . . .	195

CHAPTER 8 Principles of Hoisting, Rigging, and Slings 197

Introduction	198
Purpose, Usage, and Types of Lifting and Blocking Equipment and Devices	199
OSHA Standards for Proper Lifting Techniques and Equipment	210
Wire Rope Application and Use	212
Winch Design, Operation, and Troubleshooting . . .	213
Towing, Transporting, and Coasting Precautions . .	214
Ready for Review	216
Key Terms	216
Review Questions	217
ASE Technician A/Technician B Style Questions . .	218

SECTION II Electrical & Electronic Systems

CHAPTER 9 Principles of Electricity and Electrical Circuits 222

Introduction	223
Electrical Fundamentals	223
Conductivity	226
Understanding Current	226
Direction of Current Flow	230
Direct Current and Alternating Current	232
Heating Effect of Current	233
Electrical Versus Electronic Circuits	233
Ready for Review	235

Key Terms	235
Review Questions	236
ASE Technician A/Technician B Style Questions . .	237

CHAPTER 10 Electrical Circuits and Circuit Protection 238

Introduction	239
Circuit Classification	239
Current Flow in Circuits	243
Circuit Malfunctions	246
Circuit Protection Devices	249
Inspecting and Testing Circuit Protection Devices	253
Relays, Magnetic Switches, and Solenoids	253
Ready for Review	257
Key Terms	258
Review Questions	258
ASE Technician A/Technician B Style Questions . .	259

CHAPTER 11 Electrical Test Instruments . . . 261

Introduction	262
Electrical Test Instruments	262
Electrical Measurement with Multimeters	265
Circuit Tracers	271
Graphing Meters and Oscilloscopes	272
Electronic Service Tools	273
Ready for Review	275
Key Terms	275
Review Questions	275
ASE Technician A/Technician B Style Questions . .	276

CHAPTER 12 Batteries and Battery Services 278

Introduction	279
What Is a Battery?	279
Battery Classifications	279
Types and Classifications of Batteries	282
Sizing and Terminal Configuration	287
Battery Ratings	288
Charging and Discharging Cycle	290
Advanced Battery Technologies	292
Battery Management Systems	297
Battery Servicing, Repair, and Replacement	301
Battery Service Precautions	303
Causes of Battery Failure	304
Battery Inspecting, Testing, and Maintenance . . .	305
Charging Batteries	309
Jump-Starting Equipment	312

Measuring Parasitic Draw	312	Removing, Inspecting, and Replacing an Alternator	390
Identify and Test Low-Voltage Disconnect (LVD) Systems	313	Overhauling an Alternator	390
Recycling	313	Ready for Review	392
Ready for Review	314	Key Terms	392
Key Terms	316	Review Questions	393
Review Questions	317	ASE Technician A/Technician B Style Questions ..	393
ASE Technician A/Technician B Style Questions ..	317		
CHAPTER 13 Electric Motors	319	CHAPTER 16 Electrical Sensors, Sending Units, and Alarm Systems	395
Introduction to Electric Motors	320	Introduction	396
Advantages of Electric Motors	321	Types of Sensors	396
Classification of Electric Motors	323	Sensors and Position Calculations	410
AC Current Types	325	Sensor Fault Detection Principles	412
AC Motor Construction and Classification	331	Ready for Review	423
Ready for Review	340	Key Terms	424
Key Terms	340	Review Questions	425
Review Questions	341	ASE Technician A/Technician B Style Questions ..	425
ASE Technician A/Technician B Style Questions ..	341		
CHAPTER 14 Starting Systems	343	CHAPTER 17 Electrical Instrumentation and Alarm Systems	427
Introduction	344	Introduction	428
Fundamentals of Starting Systems and Circuits ..	344	Warning Lights and Gauges	428
Types of DC Motors	348	Operator Information Screens	435
Components of Starters	351	Troubleshooting Instrument Gauge Problems ..	437
Starter Control Circuits	355	Ready for Review	440
Starting System Testing	358	Key Terms	440
Starter Current Draw Testing	362	Review Questions	440
Testing Starter Circuit Voltage Drop	363	ASE Technician A/Technician B Questions	441
Inspecting and Testing the Starter Control Circuit ..	363		
Inspecting and Testing Relays and Solenoids	364	CHAPTER 18 Principles of Machine Electronic Control Systems and Signal Processing	443
Removing and Replacing a Starter and Inspecting the Ring Gear or Flexplate	365	Introduction	444
Overhauling a Starter Motor	366	Benefits of Electronic Control	444
Ready for Review	367	Elements of Electronic Signal-Processing Systems	447
Key Terms	368	Types of Electrical Signals	448
Review Questions	368	Processing Function	455
ASE Technician A/Technician B Style Questions ..	369	Ready for Review	458
		Key Terms	459
		Review Questions	459
		ASE Technician A/Technician B Style Questions ..	460
CHAPTER 15 Charging Systems	371		
Introduction	372	CHAPTER 19 Onboard Networks Systems	462
Alternator Functions	372	Introduction	463
Alternator Construction	375	Machine Onboard Networks	463
Charging System Diagnosis	386	Network Construction and Classification	464
Charging System Output Test	388		
Testing Charging System Circuit Voltage Drop ..	389		
Inspecting, Repairing, or Replacing Connectors and Wires of Charging Circuits	390		

Time Division Multiplexing	465
Controlled Area Networks	469
Diagnosing Network Communication Problems	475
Ready for Review.	477
Key Terms.	478
Review Questions	478
ASE Technician A/Technician B Style Questions . . .	479

CHAPTER 20 Onboard Diagnostic

Systems	481
Introduction.	482
Fundamentals of Onboard Diagnostics	482
Self-Diagnostic Capabilities and Approaches.	483
Ready for Review.	491
Key Terms.	492
Review Questions	492
ASE Technician A/Technician B Style Questions . . .	493

CHAPTER 21 Automated Machines, Telematics, and Autonomous Machine Operation

Operation	495
Applications of Autonomous and Self-Steering Machines.	496
An Overview of Automated Machine Operation.	497
Classifications of Autonomous Systems	499
Enabling Technologies for Machine Automation . . .	504
Global Positioning Systems	508
Telematics	517
Remote Control	518
Automated Steering.	519
Machine Safety with Radio and Other Wireless Technology.	522
Ready for Review.	523
Key Terms.	524
Review Questions	525
ASE Technician A/Technician B Style Questions . . .	526

SECTION III Fluid Power

CHAPTER 22 Fundamentals of Hydraulics

of Hydraulics	530
Introduction.	531
Fundamentals of Hydraulics.	531
Hydraulic System Terminology	532
Advantages and Disadvantages of Hydraulic Systems.	533

Pascal's Law and Hydraulic Systems.	534
Bernoulli's Principle	535
Measurement Units for Hydraulic Systems.	535
Hydraulic Pressure and Flow.	536
Positive and Negative Pressure	537
Organizational Bodies Governing Industrial Standards	538
Calculating Force, Pressure, and Area	538
Safety Concerns Related to Hydraulic Systems . . .	542
De-energizing a Hydraulic System.	544
Ready for Review.	544
Key Terms.	545
Review Questions	545
ASE Technician A/Technician B Style Questions . . .	546

CHAPTER 23 Hydraulic Components—

Principles of Operations.	548
Introduction.	549
Types and Applications of Hydraulic Systems Used for Mobile Off-Road Equipment.	549
Components of Basic Hydraulic Systems	551
Operating Principles of Hydraulic System Components	552
Operation of a Basic Hydraulic System.	562
Calculating Cycle Times and Hydraulic Horsepower.	563
Basic Hydraulic Schematic Symbols.	565
Ready for Review.	569
Key Terms.	570
Review Questions	571
ASE Technician A/Technician B Style Questions . . .	572

CHAPTER 24 Hydraulic Reservoirs

Introduction.	574
Purpose and Fundamentals of Hydraulic Reservoirs	574
Types and Construction Features of Hydraulic Reservoirs	574
Principles of Operation of Hydraulic Reservoirs	580
Identify the Types and Construction Features of Hydraulic Reservoirs	581
Inspect Hydraulic Reservoirs Following Manufacturers' Recommended Procedures . . .	581
Perform a Reservoir Drain and Cleanout Procedure Following Manufacturers' Recommendations for Hydraulic Reservoirs. . .	582
Ready for Review.	583

Key Terms	584
Review Questions	584
ASE Technician A/Technician B Style Questions	585
CHAPTER 25 Hydraulic Pumps	586
Introduction	587
The Purpose and Fundamentals of Hydraulic Pumps	587
Types and Construction Features of Hydraulic Pumps	588
Operation of Hydraulic Pumps	595
Hydraulic Pump Performance Calculations	601
Diagnosing Hydraulic Pump Problems	604
Hydraulic Pump Reconditioning and Repairs	605
Common Causes of Pump Failure	606
Reconditioning Hydraulic Pumps	607
Remove and Install a Hydraulic Pump, Following Manufacturer's Service Information	607
Ready for Review	608
Key Terms	609
Review Questions	610
ASE Technician A/Technician B Style Questions	610
CHAPTER 26 Hydraulic Valves	612
Introduction	613
Purpose and Fundamentals of Hydraulic Valves	613
Types and Construction Features of Hydraulic Valves	613
Principles of Operation of Pressure Control Valves	614
Operating Principles of Hydraulic Flow Control Valves	623
Principles of Operation of Hydraulic Directional Control Valves	626
Common Causes of Valve Failures	637
Inspect, Diagnose, and Adjust Hydraulic Valves	638
Recommend Reconditioning or Repairs of Hydraulic Valves	639
Ready for Review	640
Key Terms	641
Review Questions	642
ASE Technician A/Technician B Style Questions	643
CHAPTER 27 Hydraulic Actuators	644
Introduction	645
Purpose and Fundamentals of Hydraulic Actuators	645
Functions and Applications of Hydraulic Actuators	647
Hydraulic Actuator Construction	648
Seals on Hydraulic Actuators	653
Common Causes of Actuator Failure	655
Calculating the Force or Pressure of a Hydraulic Cylinder	655
Calculating Hydraulic Cylinder Speed	657
Understanding Torque	657
Hydraulic Motor Calculations	658
Testing, Diagnosing, and Trouble-Shooting Actuator Problems	658
Inspection and Repair Procedures	660
Ready for Review	662
Key Terms	662
Review Questions	662
ASE Technician A/Technician B Style Questions	663
CHAPTER 28 Hydraulic Fluids and Conditioners	664
Introduction	665
Purpose and Fundamentals of Hydraulic Fluids	665
Composition and Properties of Hydraulic Fluids	667
Purpose and Fundamentals of Hydraulic Fluid Conditioning	672
Function and Construction Features of Hydraulic Fluid Filters	677
Functions and Construction Features of Hydraulic Fluid Heaters and Coolers	683
Perform a Post-Failure External Filtration Procedure	684
Ready for Review	685
Key Terms	686
Review Questions	687
ASE Technician A/Technician B Style Questions	687
CHAPTER 29 Hydraulic Conductors and Connectors	689
Introduction	690
Hydraulic Pressure in a Closed System	691
Safety Requirements for Hydraulic System Conductors and Connectors	691
Construction Features of Hydraulic Lines	692
Construction Features of Hydraulic Hoses	695
Working Pressure and Burst Pressure Ratings for Conductors	698
Conductor Sizing	698

Conductor Failures	699	Load sensing.	761
Hydraulic Connectors	700	Pressure- and Flow-Compensated Hydraulic Systems.	765
Construction Features of Hydraulic Seals.	705	Hydraulic Pilot Controls	769
Construction Features of Hydraulic Quick Couplers.	706	Purpose and Fundamentals of Electronically Managed Hydraulic Systems.	770
Ready for Review.	707	Principles of Operating Electronically Managed Hydraulic Systems	772
Key Terms.	707	Excavator Hydraulic Systems.	777
Review Questions	708	Construction Features of Electronically Managed Hydraulic Systems.	784
ASE Technician A/Technician B Style Questions . .	708	Inspect, Test, and Diagnose an Electronically Managed Hydraulic System	786
CHAPTER 30 Hydraulic Accumulators and Accessories	710	Ready for Review.	791
Introduction.	711	Key Terms.	792
Types of Accumulators.	711	Review Questions	792
Safety Precautions for Hydraulic Accumulators.	714	ASE Technician A/Technician B Style Questions . .	793
Hydraulic Oil Coolers	714	CHAPTER 33 Graphic Symbols and Schematics	794
Water-Cooled Hydraulic Coolers and Their Operation.	716	Introduction.	795
Hydraulic Heaters	717	Schematic Legends and Symbols	795
Symbols for Accumulators, Coolers, and Heaters	719	Ready for Review.	808
Ready for Review.	719	Key Terms.	809
Key Terms.	720	Review Questions	810
Review Questions	720	ASE Technician A/Technician B Style Questions.	811
ASE Technician A/Technician B Style Questions . .	721	CHAPTER 34 Preventive Maintenance.	813
CHAPTER 31 Hydrostatic Drives	722	Introduction.	814
Introduction.	723	Regular Hydraulic System Maintenance	814
Purpose and Fundamentals of Hydrostatic Drives.	724	Ready for Review.	822
Principles of Operation of Hydrostatic Drives . .	729	Key Terms.	823
Types and Construction Features of Hydrostatic Drives.	732	Review Questions	823
Inspect, Test, and Diagnose Hydrostatic Drives.	747	ASE Technician A/Technician B Style Questions . .	824
Reconditioning or Repairs Following Manufacturers' Recommendations for Hydrostatic Drives.	750	CHAPTER 35 Troubleshooting and Diagnostics	825
Ready for Review.	752	Fundamentals of Diagnosing Hydraulic Systems.	826
Key Terms.	753	Troubleshoot Hydraulic Systems.	826
Review Questions	754	Hydraulic Systems Testing Equipment	826
ASE Technician A/Technician B Style Questions . .	754	Hydraulic System Problems and Remedies	828
CHAPTER 32 Advanced Hydraulics	756	Diagnostic Procedures.	835
Introduction.	757	Ready for Review.	839
Open Center Versus Closed Center Hydraulic Systems.	758	Key Terms.	840
Variable Displacement Pump Controls	760	Review Questions	840
		ASE Technician A/Technician B Style Questions . .	840

SECTION IV Wheeled Equipment and Attachments

CHAPTER 36 Wheels, Tires, and Hubs 844

Introduction	845
Wheels	845
Tires	847
Wheel Hubs	853
Ready for Review	856
Key Terms	856
Review Questions	857
ASE Technician A/Technician B Style Questions . . .	857

CHAPTER 37 Operators Station. 859

Introduction	860
Fundamentals of Operator Stations	860
Machine Controls	861
Telematic Systems and GPS Guided Machines . . .	865
Operator Protection Systems	866
HVAC Systems	868
Servicing and Repairing HVAC Systems	880
Ready for Review	886
Key Terms	887
Review Questions	887
ASE Technician A/Technician B Style Questions . . .	888

CHAPTER 38 Machine Frames and Suspension Systems. 890

Introduction	891
Fundamentals of Off-Road Equipment Frames . . .	891
Types of Frames	893
Frame Repair	894
Suspension System Fundamentals	895
Off-Road Equipment Suspension Types	896
Track Machine Suspension Systems Track	
Roller Bogie Systems	904
Diagnosing Suspension Systems	905
Servicing Suspension Systems	906
Ready for Review	908
Key Terms	908
Review Questions	909
ASE Technician A/Technician B Style Questions . . .	909

CHAPTER 39 Conventional Steering Systems 911

Introduction	912
Types of Conventional Steering Systems	913
Steering System Components and Operation . . .	921

Steering Service	925
Ready for Review	929
Key Terms	930
Review Questions	930
ASE Technician A/Technician B Style Questions . . .	931

CHAPTER 40 Wheeled and Tracked Drive Working Attachments 933

Introduction	934
Attachment Types and Functions	934
Attachment Adjustments and Maintenance	941
Locating and Following OEM Service	
Procedures	942
Performing Operational Tests	943
Component Inspection, Removal,	
and Replacement Procedures	944
Justifying Component Replacement and Service . .	944
Ready for Review	945
Key Terms	946
Review Questions	947
ASE Technician A/Technician B Style Questions . . .	948

SECTION V Track Drive Undercarriage & Working Attachments

CHAPTER 41 Track Drive Undercarriage Systems 952

Introduction	953
What Is Track Drive Undercarriage?	953
Track Drive Components and Operation	957
Steel Track Undercarriage	960
Track Chains	966
Track Guidance System	976
Rubber Track	981
Ready for Review	986
Key Terms	987
Review Questions	988
ASE Technician A/Technician B Style Questions . . .	989

CHAPTER 42 Undercarriage Inspection and Maintenance 991

Introduction	992
Undercarriage Wear Factors	992
Track Component Wear	1002
Track Drive Undercarriage Inspection,	
Adjustment, and Repair	1009
Track Technician Consultation	1024

Ready for Review	1026
Key Terms	1028
Review Questions	1028
ASE Technician A/Technician B Style Questions . .	1029

SECTION VI Power Transfer Systems

CHAPTER 43 Friction Clutches 1032

Introduction	1033
Fundamentals of Clutches	1033
Types and Design of Clutches	1034
Clutch Actuation Systems	1044
Clutch Operation	1045
Preventive Maintenance of Clutches	1047
Troubleshooting Clutch Failures and Problems	1050
Other Clutch Types Used with Mobile Off-Road Equipment	1050
Ready for Review	1053
Key Terms	1054
Review Questions	1055
ASE Technician A/Technician B Style Questions . .	1056

CHAPTER 44 Gearing Basics 1057

Introduction	1058
Gear Basics	1058
Gear Ratio Calculations	1061
Types of Gears	1064
Planetary Gears	1067
Planetary Gear Power Flows	1068
Ready for Review	1072
Key Terms	1073
Review Questions	1074
ASE Technician A/Technician B Style Questions . .	1074

CHAPTER 45 Manual Transmissions 1076

Introduction	1077
Fundamentals of Transmissions	1077
Transmission Types	1078
Operation and Power Flows of Manual Transmissions	1081
Single and Multiple Countershaft Transmissions Power Flows	1084
Standard Transmission Servicing	1090
Power Take-Off Devices	1094
PTO Installation	1095

PTO Service and Repair	1095
Transfer Cases	1096
Ready for Review	1097
Key Terms	1097
Review Questions	1098
ASE Technician A/Technician B Style Questions	1099

CHAPTER 46 Automated Transmissions . . 1100

Introduction	1101
Fundamentals of Automated Transmissions	1101
Types of Automated Transmissions	1102
Operation and Power Flows of Automated Manual Transmissions	1103
Troubleshooting Automated Manual Transmissions	1118
Ready for Review	1121
Key Terms	1122
Review Questions	1122
ASE Technician A/Technician B Style Questions . .	1123

CHAPTER 47 Torque Converters 1125

Introduction	1126
Fundamentals of Fluid Couplers, Torque Converters, and Torque Dividers	1126
Components of Fluid Couplers, Torque Converters, and Torque Dividers	1127
Operation of Torque Converters and Torque Dividers	1131

CHAPTER I

Introduction to MORE Applications

Knowledge Objectives

After reading this chapter, you will be able to:

- **K01001** Classify off-road and mobile equipment according to application and industry.
- **K01002** Identify and describe the purpose and functions of off-road mobile equipment.
- **K01003** Identify design factors for the selection of mobile off-road equipment (MORE).
- **K01004** Outline and describe the job requirements of MORE technicians.
- **K01005** Describe and perform pre-start and walk-around inspections.
- **K01006** Identify the work and responsibilities of MORE technicians.

Skills Objectives

After reading this chapter, you will be able to:

- **S01001** Perform a pre-start and walk-around inspection of wheeled equipment.

► Introduction

For the past 10 years, the mobile off-road heavy equipment industry has had an annual growth rate of close to 6% world-wide. The equipment which includes a vast variety of machines ranging from bulldozers, pavers, excavators, backhoes, wheel loaders, graders, agricultural tractors, cranes, and forklifts is expected to have an 8.9% annual growth from 2015 to 2020 (FIGURE I-1). Mining and material-handling equipment sales are expected to be even higher. And loaders, used primarily to move earth, are expected to account for more than 44% of the 2020 market revenue growth. The spinoff of such growth is an increased in demand for heavy equipment technicians. As new equipment is purchased to build our transportation infrastructure, extract resources, increase farm production, or refurbish old buildings, more technicians with an even greater array of skill sets are needed to service new technology.

► Skills and Responsibilities of MORE Technicians

K01006

Many skills useful just a few years ago are now outdated as new machine technologies to increase driver safety, comfort, machine productivity, and reliability are creating new competencies for technicians to adopt. Just a few examples of technological advancements include the use of machine telematics to monitor and control machine operations from a distance, advanced engine emission, fuel and control systems, and GPS guidance used by self-steering, autonomous and semi-autonomous driverless machines systems. Radical changes are taking place in the operation and control of hydraulic systems; the use of hybrid propulsion systems and advanced energy saving are some other technological

FIGURE I-1 Example of the variety of equipment classified as off-road heavy duty using mobile hydraulic systems.

You Are the Mobile Heavy Equipment Technician

While performing a routine chassis lubrication of a wheel loader used in an underground mining operation, the shift crew leader announced it was time for a short work break. To keep your lever-operated hand-held grease gun clean while on break, you wrapped the gun in a cloth shop rag. To make sure you didn't misplace the grease gun, you then temporarily stored it inside the engine compartment since the access doors were open. However, while resting on your break, a supervisor walked by, noticed the grease gun, and reprimanded you for placing the grease gun where you thought it would be secure. Reflecting on the incident days and months later, you better appreciated the seriousness of the incident if the machine had been moved or you inadvertently left the grease gun in the engine compartment.

1. What might have happened to the grease gun and rag if they were left in the area of the engine compartment?
2. How different would a fire in the engine compartment of an underground equipment be compared to one above ground?
3. Is it likely that an operator pre-start inspection would have discovered a misplaced grease gun wrapped in a rag?

FIGURE I-2 Hybrid machines such as this loader utilize an electric motor between the engine and transmission reducing both fuel consumption and emissions.

trends that technicians must master alongside traditional technologies (**FIGURE I-2**). To meet these challenges, this chapter intends to help technicians begin to understand the field of off-road equipment service. It will identify what features help define off-road equipment to bring some order to the wide range of machines comprising the industry. Major technological milestones of the off-road equipment industry and factors that shape equipment design are also surveyed to provide a foundation for details of equipment construction and operation presented in later chapters. Finally, the chapter outlines heavy-duty (HD) off-road technician job descriptions and what expectations technicians can have in the industry.

► Pre-start Safety Inspection

K01005, S01001

It's important to ensure that whenever any machine is about to be used, it is mechanically safe and capable of performing the job it's designated to do. In fact, occupational health and safety

laws in every jurisdiction require a procedure for inspecting, testing, and maintaining the safe operation of a vehicle on a daily basis. Furthermore, records must be kept of each inspection, including any notes made to identify items requiring maintenance actions. Each employee that uses a piece of equipment must perform a pre-start on that piece of equipment. This includes technicians. If a proper pre-start inspection was not performed, whoever was using the machine could be responsible for injuring themselves or someone else. Also, in some jurisdictions, it is a serious matter if a workplace safety inspector noted a defect with the equipment and a record on an inspection sheet or card was not made. To prevent the likelihood of a serious injury, fatality, or the loss of productivity due to equipment break down, it is important to first learn how to perform a pre-start inspection. These usually take 10 to 15 minutes depending on the type of equipment. Any user of the machine must also be properly trained to use the equipment and understand what is required to be inspected on the equipment. Generally, the steps outlined in **SKILL DRILL I-1** are incorporated into all pre-start inspections.

SKILL DRILL I-1 Pre-start Inspection

1. Inspect the area around the machines for:
 - tripping hazards
 - overhead hazards (i.e., loose rock, wires).

Place at least two wheel chocks around the machine tires or track or ensure wheel chocks are in place. Stop and correct any hazards before proceeding further. If hazards cannot be corrected, they must be somehow controlled and noted on a safety inspection sheet or card.

2. Perform a visual circle check. Walk around the unit and check for:
 - damaged or worn parts/wires
 - wheel chocks

- seat belts
- housekeeping cleanliness
- tire wear/pressure (visually)
- fire hazards
- overall condition of the unit.

Check also that all parts, accessories, attachments, handles, and so on are attached in place and that nothing has come loose:

- wheel nuts
- hoses
- electrical connections

SKILL DRILL 1-1 Pre-start Inspection (Continued)

- fire extinguisher
- fire suppression device.

Flammable materials near engine components create a high potential for fire, jeopardizing the safety of fellow workers, increasing downtime, and damaging to equipment. Make sure there are no dirty rags, lunch bags, spray paint cans, aerosol cans of any kind, or newspapers on the machine.

3. Check all levels, such as oil, coolant, and fuel levels. If the machine uses an automatic lubrication system, check the level of grease in the reservoir.
4. Start the equipment and inspect:
 - all lights
 - horns
 - temperatures/pressure gauges, and
 - other information systems.

Record the hour meter reading on your pre-start checklist.

5. Perform another circle inspection while the equipment is running, and check for:
 - leaking hoses
 - leaking fuel lines
 - missing or damaged lights.

6. Test all operating systems:
 - back-up alarms
 - braking systems
 - steering
 - hoisting or hydraulic systems.

After the machine has started and is being used, be aware of any changes in machine condition. For example, has the machine struck any object or been struck? Does the sound of the engine seem different? Are there any unusual smells? Are there any unusual noises or vibrations?

► What Is Mobile Off-Road Heavy Equipment?

K01002

Heavy equipment is a general term referring to a spectacularly diverse category of vehicles, operated off of roads and highways with purpose-built designs to perform a wide variety of industrial tasks. While the equipment may share many features of on-road vehicles constructed primarily to transport people and goods at high speeds, mobile, off-road heavy equipment functions in broad, non-transportation industry sectors, such as earth moving, mining, agriculture, construction, forestry, landscaping, and material handling. This category of machinery is also known by various other terms, such as heavy machine, heavy hydraulics, mobile hydraulics, construction equipment, or engineering equipment, and both rail and marine equipment are sometimes included in this category. A more authoritative definition for off-road equipment is provided by the Code of Federal Regulations (CFR), developed in the United States. This administrative legislation governing transportation defines off-road equipment as a vehicle having attached components designed to work in an off-road environment or designed to operate at low speeds, making them unsuitable for normal highway operation. Unloaded vehicle speeds should not exceed 45 mph, and there should be no capacity to carry occupants other than the driver and operating crew. In addition to those qualifications needed to classify a machine as off-road, the CFR adds that the machine may have at least one axle with a gross axle weight rating (GAWR) of 29,000 pounds or more and operates with limited speed (FIGURES 1-3 and 1-4). Note that recreational and sport utility vehicles that operate off-road would not fit this description and are regulated by different legislation.

FIGURE 1-3 The bulldozer is a classic example of an off-road machine. Its slow speed, capacity to move heavy loads, and use of tracks to navigate off-road terrain align with a definition of off-road heavy-duty equipment.

FIGURE 1-4 The mini-excavator, while not heavy in comparison to other off-road equipment, fits the CFR definition for off-road equipment.

While diverse in countless ways such as size, power, weight, function, and application, three things are distinctive about the off-road category of mobile equipment:

1. The use of fluid power attachments

Most types of off-road equipment use fluid power systems to operate equipment attached to the vehicle. **Fluid power** refers to both air and hydraulic systems transferring power to machine implements and accessories that perform the cutting, lifting, dragging, paving, sweeping, pushing, drilling, pumping, loading, digging, and dumping actions that off-road equipment is specifically designed for. Fluid power systems will use actuators that convert the energy in hydraulic fluid or compressed air into mechanical movement (**FIGURE I-5**). Movement can be linear or rotational. Cylinders containing pistons are a common example of a linear actuator. Buckets, blades, harvesters, shovels, rippers, vibrating rollers, compacters, lifting forks, and brooms are just a few examples of equipment attached to off-road machines that use linear or rotary actuators (**FIGURE I-6**). These additional accessories or implements create additional and unique power demands on the machine's engine not typically found in on-highway equipment, where the engine is used primarily for propulsion.

Fluid power not only operates equipment implements but also transfer force developed by the engine or electric motor to move the machinery. For example, engine-driven hydraulic pumps commonly supply the hydrostatic drive or hydraulic motors used by propulsion systems. The term **hydrostatic** refers to the transfer of energy through hydraulic fluids through flow and pressure (**FIGURE I-7**). This is different from **hydrodynamic** systems, which convert kinetic energy contained in the hydraulic flow into mechanical movement. A fluid coupling, also known as a hydrodynamic clutch, is an example of a hydrodynamic device. Compressed air distribution systems are installed in underground mines to operate compressed air drive motors and implements. With the absence of electric sparks and noxious engine emissions, compressed air minimizes health and safety hazards to workers and the risk of explosion due to hazards from combustible gases and dust.

2. They are mobile

Off-road propulsion systems are unique and specially adapted to the operating terrain and other ground conditions where they are used. Soft, uneven, rugged ground conditions encountered while working in farm fields, forests, mines, or quarries or on an earth-moving project means that not only is the machine designed to maneuver well and supply extra traction force for moving loads but also that it should not sink or slip. Steering systems will commonly supply additional maneuverability in confined spaces. The work required of forklifts where the rear axle steers, or articulated loaders, are examples of a machine design adaptation for improved maneuverability (**FIGURE I-8**). **Differential steering** (or skid steering), where one track will turn at a different speed than the other, provides even the largest machines with exceptional

FIGURE I-5 A simple hydraulic circuit. Actuators are devices that convert the energy of pressurized oil or air into movement. The hydraulic cylinder is an example of a linear actuator.

Changing Direction of Oil Flow to Control Valve

No Movement

Retract Up

Push Down

FIGURE I-6 Supplying pressurized oil to either side of the piston in this linear actuator causes the bucket to lift or lower.

FIGURE I-7 Hydraulic motors or travel motors are used to propel this excavator. “Hydrostatic drive” is the technical term given to rotary actuators used for a machine travel system. All other operations of the excavator are controlled using hydraulic devices.

FIGURE I-8 An articulated dump bends or articulates between the dump box and the cab. Bending gives the vehicle extra maneuverability around obstacles.

FIGURE 1-9 Differential steering, sometimes called skid steering, applies drive torque to one track while braking or reversing the direction of the opposite track.

maneuverability (**FIGURE 1-9**). Off-road vehicles are often stationary when working, and they infrequently exceed 10 mph or 6 km/hour when traveling.

3. They are self-powered

Off-road equipment is made mobile by drivetrain or propulsion systems, which are electric, hydraulic, or mechanical. In mechanical systems, a geared transmission, drive belts, or chains are used to transmit torque to wheels or the track undercarriage. Hydraulic force rotates drive motors in hydrostatic drive systems or couples engines with transmissions using torque converters or fluid clutches. Electric motors are more commonly used in emission-sensitive work environments such as underground mining or power lift equipment where exhaust from engines can harm workers. Hybrid electric drive systems have recently been developed and are used in excavators and bulldozers to reduce fuel consumption.

The term **prime mover** is a technical term that describes the principal device used to produce mechanical energy in off-road equipment, propelling the machine and supplying specialized equipment attachments. For example, a machine powered with only electricity to operate a motor would have its electric motor designated the prime mover. A diesel engine's high torque output, low fuel consumption, durability, and relatively low maintenance requirements make this energy source the prime mover of choice for HD off-road machines.

SAFETY TIP—Why Is HD Off-Road Equipment Painted Yellow?

Various colors and graphical symbols are used in many places on off-road equipment. Operating control symbols, instrumentation, and specific colors are used to designate functions or hazards in a universal language. The correct color can provide immediate information and warnings of hazards that are essential to work safety. Yellow is a color designated by OSHA—Occupational Health and Safety—as the basic color that

should warn anyone and encourage them to exercise additional caution, and it marks physical hazards such as striking against, stumbling, falling, tripping, and “caught in between.” Yellow is also one of the most visible colors in low light situations.

► Development Milestones of Off-Road Mobile Equipment

K01001

Internal Combustion Engines

The off-road heavy equipment industry is a relatively new enterprise. Until the beginning of the 1900s the use of machines to dredge, dig, thresh, plow, lift, haul, and reshape the natural landscape could not begin in earnest without the development of two key technologies: off-road propulsion systems and a mobile source of power. With the introduction of steam engines and later internal combustion engines such as the diesel engine, the centuries-old practice of using animal power to pull equipment, and humans to operate hand shovels or wheelbarrows, gave way to the use of far more powerful and increasingly sophisticated machines. Untethered from the need for wind power, water wheels, or even the use of animals, evolving engine technology at the turn of the last century dramatically accelerated the development of this new category of machines. Engines provided power to not only move the machines around off-road worksites but also to operate cables and fluid power systems for unique, purpose-built machines used to perform specialized jobs. Increasing engine power output provided the torque to perform more work in less time, multiplying machine efficiency. Using fluid power principles can produce extreme mechanical advantage which when harnessed, multiplies the mechanical power of an engine (**FIGURE 1-10**). For example, just under nine horsepower of hydraulic power is needed to lift five tons a height of one foot in three seconds (**FIGURE 1-11**).

FIGURE 1-10 Note that using a small amount of force acting on the smaller piston's surface area can multiply the force exerted by the larger piston. The use of hydraulics enables the use of a high ratio of mechanical advantage.

Fluid Power Principles

Calculate the horsepower provided by the system below to lift a 10,000 lb force in 3 s.

FIGURE 1-11 Calculating the conversion of horsepower to hydraulic power.

Track Undercarriage

Unique propulsion systems that have been better adapted to off-road use were a second major development that greatly advanced the evolution of mobile equipment. Off-road machinery is not designed to travel long distances carrying goods and people. Instead, the equipment typically moves more slowly over ground conditions such as farm fields, forests, mines, snow, mud, gravel, and rock and in loose dirt. Often requiring enormous traction force to push, carry, or dump heavy loads in these rugged, uneven terrains, equipment mobility is enhanced by transmitting traction force through continuous track-type or specialized wheeled-drive systems. Tracked machines, or crawlers as they are sometime called, are the best propulsion system for traveling over soft, loose, uneven ground conditions. Tracked equipment uses long rubber belts or linked metal plates called **track shoes** connected to produce a caterpillar-like movement (**FIGURE 1-12**). Track system components are collectively called the track **undercarriage**, which uses long rolling track to distribute heavy machine weight over a wide track shoe or belt width. Track systems have much more surface area in contact with the ground than the contact patch that wheeled equipment has equipment has with its use of rubber tires mounted on metal wheel rims. Multiplying track dimensions of width and length and then dividing the weight of even the heaviest of machines illustrates that a tracked machine has the advantage of providing lower **ground pressure**, which can easily be less than 10 psi. Low ground pressure track is better adapted to soft fertile soils of rich farmland and forests or to loose, soggy dirt and gravel. Not only would heavy machinery using track systems not easily sink, but the greater track surface area brought about by using the cleat-like features on track shoes and belts also provides greater traction force. These cleat like features found in track shoes are called **grouser** bars.

The first commercial continuous track vehicle was a steam-powered log hauler demonstrated in England in 1901. Just a few years later, Benjamin Holt purchased the patent rights for the track system and immediately applied the technology to tractors cultivating California farmland in the United States.

FIGURE 1-12 The track drive undercarriage on this bulldozer links metal track shoes together into a continuously rotating belt, which is used to propel the machine and provide additional traction force.

This early adopter of track drive undercarriage founded the Holt Manufacturing Company to produce tractors used for farming. In time, World War I British soldiers dubbed tanks using Holt's steel track drives Holt's tracked machines "caterpillars" because of the comparable movement of track drive propulsion. The name caterpillar stuck to Holt's equipment, which was later used when Holt merged with another company, the C.L. Best Tractor and formed Caterpillar Company in 1925. The versatility of tractors to navigate soft, churned ground encountered in logging and road-building operations led to the development of the military tank in World War I. During that conflict, Winston Churchill conceived of the idea of weaponizing the tractors while watching them haul equipment and supplies. Since that time, track drive propulsion became widely used by a huge variety of off-road machinery—in particular, by bulldozers.

Wide Base Pneumatic Tires

While many types of equipment use steel or rubber-belt continuous tracks systems to travel over severe service ground conditions, tires are used where higher speed or mobility is required. That development couldn't take place until the 1930s, when pneumatic tires were introduced. The first application of pneumatic tires for off-road equipment was in 1932 when an Allis Chalmers tractor in Waukesha Wisconsin had Firestone aircraft tires installed. Until then, the narrow, solid rubber tires used by on-road vehicles were quite useless. Wide steel or even wooden wheels with cleat-like projections were used instead of tires on tractors until specialized tire production got underway. However, since first being used on agricultural tractors in the 1930s, wide base pneumatic tires have become the dominant traction device for agricultural tractors and implements. Pneumatic tires' superior speed, maneuverability, and reliability in comparison to track drive undercarriage make them the preferred choice for agriculture applications. Rubber tires also demonstrate a 45% fuel economy advantage over slower moving, high-friction track drives. Newer rubber track systems, having many of the same advantages offered by metal track systems, are now ending the dominance of pneumatic tires in that category, enabling track drive to overcome the higher maintenance and initial acquisition cost associated with track undercarriage.

When using **ballast**, off-road tires offer more stability, which helps to prevent tire slippage in various soil conditions and to lower a machine's center of gravity (**FIGURE I-13**). In addition to inflating the tire with air, adding ballast involves filling the tire to between 40% and 75% full with a liquid that will not freeze—or filling it with a denser mixture of water and calcium chloride slurry, providing even more weight. When used on equipment with tall tires and high axle clearances, the additional ballast helps prevent vehicle tipping. When filled with ballast, heavier tires are less prone to slipping, spinning, hopping, or axles lifting off the ground. The load-bearing capabilities of tires filled with ballast increases substantially over tires filled with only air.

Tire design for off-road equipment categorizes tires by service. Tread types are differentiated for use on hard-packed, soft, smooth, and rocky ground surfaces (**FIGURE I-14**). Depending on

FIGURE I-13 Tire ballast in these four tires is close to 12.5 tons. Ballast helps stabilize high center of gravity machines to prevent tipping and prevents tire slippage.

the load they must support and the terrain encountered, each type of slow-moving equipment will have a unique tire designation.

Replacement of Cable Systems with Mobile Hydraulic Systems

A third major technological development driving the evolution and sophistication of off-road machinery is the addition of hydraulic systems. Hydraulic systems on mobile equipment are used to transfer and control power on a wide variety of attachments and implements. While hydraulic systems appear universal everywhere today, it wasn't until the 1960s that construction and agricultural equipment began to switch from using cable-operated systems. Bulldozer blades and excavator buckets all relied on winches and wire ropes that used mechanical clutches (**FIGURE I-15**). Some older, lighter equipment relied on operators using tiresome hand cranks to manipulate cables. Development of new materials to fabricate hydraulic hoses such as nitrile rubber compatible with mineral oils was the first breakthrough to enable the use of mobile hydraulic systems. Water as a hydraulic medium corroded metals, and friction between seals and linear actuators quickly led to leaky seals. Steam had an identical problem. However, in the early 1950s, French equipment manufacturer Poclain and other European equipment manufacturers introduced the first fully hydraulically operated machines.

Initial resistance to the use of hydraulics was high. The usefulness of hydraulic power was first demonstrated in 1936 on a Deere tractor. The mechanical rockshaft, a three-point hitch device connecting tractors to implements such as plows

FIGURE I-14 Examples and applications of tread design used for off-road equipment applications.

FIGURE I-15 Hydraulic circuits replaced cable-operated movements of buckets blades. Instead of using a mechanical clutch, this cable winch is driven by a hydraulic motor.

or seeders, was replaced with a hydraulic rockshaft. The configuration provided a variable height and could change the angle of the implement relative to the tractor. The value of this hydraulic powered lifting device compelled all manufacturers to provide this feature, but the use of hydraulics did not quickly extend to other accessories. Problems with the earliest mobile hydraulic systems slowed rapid adoption of hydraulically operated implements and attachments. For example, early hydraulic hoses were prone to bursting, and operators perceived the first leaky hydraulic machines as dirty and underpowered. In addition to the need to constantly top up oil reservoirs due to oil loss through leakage, components operating in dusty, dirty conditions wore out quickly. This happened primarily because hydraulic systems required high filtering efficiency of hydraulic fluid to prevent premature system failures (**FIGURE I-16**).

A second reason for slow adoption was that simple cable-machine designs combining levers, pulleys, gears, wheels, and inclined planes were still relatively easy to repair and powerful enough for most of the jobs at hand. The development of more sophisticated and innovative hydraulic systems with more must-have features drove change. For example, hydraulic cylinders enabled the application of a down force on a dozer blade for digging, rather than depending on gravity. Hydraulics' ability to transfer power through pipes and tubes to linear and rotary actuators led to equipment designs that became much more powerful, productive, efficient, and durable. A greater degree of machine control for raising and lowering implements also became possible, allowing greater precision while manipulating grader and dozer blades. Rotary power for functions such

as fans, augers, saws, drills, and other traction motors could be introduced. Subsequent to refinements overcoming problems with early systems, operators rapidly adopted mobile hydraulics when they observed how blades, buckets, and booms could be moved more quickly and operated with greater force than what sluggish cables could manage.

The Advantages of Fluid Power Systems

Unleashed, the versatility and sophistication of mobile hydraulic systems has grown dramatically. Because chains, cables, sheaves, drums, friction clutches, gears, and hoisting engines were eliminated, equipment design could be simplified. In an excavator, the four cylinders that controlled the boom or stick and bucket are controlled by two joysticks today, and the operator's hand movements on each lever are instantly and accurately duplicated at the bucket. Early hydraulic systems operated with simple fixed-displacement gear pumps only actuated a single cylinder. Today, multiple hydraulic functions take place simultaneously, using vastly more efficient variable pressure and variable volume pumps. Early systems used hydraulic pressures topping out at 2,000 to 2,500 psi. High-energy flow losses took place when continuously pressurized hydraulic liquids converted pressure into heat using spring-loaded pressure-relief valves. Today, pressure-compensating and load-sensing hydraulic systems using variable displacement hydraulic pumps operate much more efficiently, using less fuel. Since the pumps supply only enough oil to maintain maximum system pressure, fuel

Swing Mechanism

- Outer race fixed at upper structure turns with the "Pinion" that spins along with the inner race fixed at the lower structure.
- The part between the outer Race and the inner Race turns smoothly on the ball bearings.

FIGURE I-16 The earliest machines to convert to hydraulics were excavators. The upper house or structure rotates using a worm gear-driven slewing ring.

or electric energy is not wasted operating the hydraulic pump since excess fluid flow is not relieved and returned to a reservoir hydraulic pressure and returning it to a reservoir. Today, typical hydraulic systems on an excavator operates between 5,000 and 6,000 psi through smaller components operating with tighter tolerances. With higher pressures, the pistons in hydraulic cylinders and other actuators can move more quickly. Increased pressure and power enable machines like excavators or loaders to apply higher pressure to dig quickly in very hard ground. Tighter tolerances allow less dirt into the system and improve system durability. Hydraulic-powered attachments such as concrete breakers, grapple hooks, or augers are rapidly attached to equipment using hydraulic quick couplers, which connect and disconnect a sealing lock ring at a hose end to simplify attachment mounting (**FIGURES 1-17 and 1-18**).

FIGURE 1-17 This hydraulically operated plate packer attaches to a skid-steer loader. Hydraulic quick connectors are used to connect the hydraulic system.

FIGURE 1-18 The quick connector on this skid-steer loader helps attach various implements, such as rotating brooms, hammers, brush cutters, or grapples.

Smart Iron refers to machines operating with sophisticated electrohydraulic control systems. Hydraulic pumps with a programmable electronic control unit (ECU) have user interface software that allows technicians to quickly set up pump-specific parameters and make calibrated adjustments for machine behavior.

Onboard communication networks, which connect all of a machine's electronic control units to exchange information, introduce new levels of safety, efficiency, and enable the use of customizable features. These onboard networks have enabled the use of advanced telematics for communication between machines and remote monitoring at locations where real-time monitoring of the equipment operation takes place. Self-steering machines and both semi-autonomous and fully autonomous machinery are made possible using onboard network communication between control units for machine hydraulics, steering, engine, powertrain, and implements.

Mobile hydraulic systems offer a long list of advantages:

- Simplified operation—fluid power systems eliminate complex mechanical systems composed of cables gears, chains, belts, and camshafts.
- Long service life, which is the result of hydraulic fluid lubricating components and acting as a cooling medium.
- High horsepower-to-weight ratio—a 5 hp hydraulic motor can easily be held in the palm of your hand, whereas a 5 hp electric motor could weigh 40 lb (18.2 kg).
- Simplified system design—a single hydraulic pump or air compressor can supply power to many cylinders, rotary motors, or other actuators.
- Actuator force or rotational torque can be held constant.
- Pneumatic and hydraulic motors can produce high torque while operating at low rotational speeds without overheating.
- Safer operation in hazardous environments since they operate spark-free.
- An ability to tolerate high temperatures.
- Equipment and operator safety due to rapid-acting overload protection by means of pressure-relief valve.
- Simple displays of load force using a line pressure measurement device.
- Variable speed adjustment to machine drive speeds using hydrostatics and the capability to instantly reverse direction of movement.

Examining the differences between pneumatic and hydraulic systems, it can be noted that while air is capable of transmitting high force and torque, it has an advantage when used for rapid-acting, repetitive applications where direction of movement is frequently reversed. Since compressed air can absorb shock loads with a cushioning effect, it supplies a gentler and smoother application force in comparison to hydraulic or electromechanical actuators. Pneumatic systems can also provide improved control and precision when pressing or squeezing. Pneumatic systems cannot provide as high a force as hydraulic fluid can.

► Off-Road Machine Design

K01003

Demand for Equipment Productivity

The benefits of labor-saving productivity provided by off-road machines are impossible to overestimate. Off-road machines have been crucial for the development of modern infrastructure enjoyed by today's civilization. Equipment development has enabled enormous social change to take place, releasing workers from agricultural settings and many other labor-intensive endeavors and allowing them to move into cities to engage in other occupations. Without the invention of the simple farm tractor and a myriad of agricultural implements accompanying its evolution, it's difficult to imagine that we would have the stable and secure food supplies that we have today. In fact, it can be effectively argued that most of today's off-road machines found across the wide spectrum of equipment industry groups have their origins in modified agricultural tractors. The broad industry groups using off-road equipment include the following:

- agriculture
- forestry
- earth moving
- mining
- material handling.

Within each of these groups are many smaller, specialized sectors. Earth moving, for example, shares common types of construction equipment used by industries such as road building, landscaping, landfill, demolition, drilling, pipe laying, paving, and others. Mining also uses many machines identical to those used in earth moving but with unique adaptations for its specialized operating conditions. The most significant factor driving differentiation of the basic machine design is a demand for productivity. **Productivity** is measured over the course of an **operating cycle** (FIGURE I-19). A generic operating cycle for many machines, such as a loader, excavator, or even a forklift, consists of three parts: loading, transporting, and unloading the material. Productivity is calculated by measuring the amount of material carried per cycle and dividing it by the total cycle time. Stated another way, machine productivity is like an equation for calculating power: the amount of work performed, divided by the time it takes to complete the work. Improving job performance or productivity is accomplished by either increasing the load-carrying capacity or shortening the cycle time.

Other Factors Affecting Productivity

Since the evolution of off-road machines is driven primarily by productivity demands, various design features, implements, and accessories are integrated into purpose-built machines uniquely adapted for the operating conditions and tasks assigned to the machine (FIGURE I-20). The following are some examples of factors influencing productivity:

1. Adding load carrying capacity of equipment is a major consideration. Bigger buckets and blades or wider tillers or mowers are examples of features to increase load-carrying

FIGURE I-19 The operating cycle of a wheel loader consists of loading product into the bucket, traveling 25 meters backward, then 18 meters forward, and then unloading the material.

abilities or the ability to do work. Clearly a larger cutting swath made by a wider mower blade will yield more productivity since more work is done during each pass through a field. However, load-carrying capacity puts further demands on the machine's power or engine size, frame, suspensions, tires, and so on.

2. Traction performance—machines depend on tires or track drive undercarriage to travel and navigate around obstacles. More work can be completed if the machine can push or pull greater weight or loads and/or move those loads faster. The terrain and the weight of the load are both considerations: Is it too soft for tires or hard enough to support the traction force of a machine and its weight?
3. Speed—the power of the prime mover, the choice of propulsion system, maneuverability, and the design of the accessories or implements used to cut, lift, grasp, or haul the load are among the many factors affecting operating cycle time. Anything that can get the job done faster will improve productivity. The use of more powerful hydraulic systems is an example of a feature that can further shorten the time needed to complete an operation.
4. Reliability, durability, and ease of maintenance—these factors are secondary to productivity demands but influence productivity since machines need to be available for as much up time or productive work as possible. These factors are significantly influenced by the skill of technicians and quality of maintenance programs.
5. Operator efficiency—the skill and ability of a machine's operator to remain focused on a task without fatigue can impact productivity. Improvements to cab layout and vehicle dynamic qualities can go a long way toward minimizing operator fatigue and to improving work safety while still increasing productivity. The ease of operation, quality of ride comfort, steering, instrument layout, suspensions, and

FIGURE 1-20 Factors influencing the design of off-road equipment.

cab environment may not be immediately thought of as important aspects of machine design, but they do affect an operator's ability to do a job well over a long shift. Being tired from stretching too far too frequently while operating controls; irritated due to poor sight lines, cab temperatures, dust, noise, or concern about risks to personal safety; distracted by the need to remain vigilant to too many warning lights, gauges, and awkwardly built levers, pedals, knobs, and switches definitely impacts machine productivity. The mandated use of **roll over protection systems (ROPSs)** and cab environment controls are not only essential to meet health and safety requirements for workers but can deeply affect how much work is performed by the end of the day.

Equipment Selection Factors

When selecting an off-road vehicle, the first question is where the machine will operate. Consider the following factors:

Maximum operating slope—a machine can be expected to operate anywhere from level ground to almost a vertical wall. If it must move up and down steep slopes, the torque applied through the wheels or track has to increase either through more powerful engines or through transmissions with greater mechanical advantages. If operated on steep slopes, the position of the machine's center of gravity must be considered to prevent overturning. Self-leveling cabs can extend the steepness of slope at which a machine operates. For example, in forest operations, tracked machines with self-leveling cabs are capable of operating on slopes up to 50% grade (**FIGURE 1-21**). Without self-leveling cabs, tracked equipment can operate on slopes up to 40%. Wheeled machines with higher centers of gravity should be restricted to slopes below 25%.

Obstacles—ground surface features, such as broken concrete, trees, landfill waste, boulders, stumps, logs, ditches, and mounds of material, can stop or slow a machine as it attempts to maneuver around the obstacle. Maneuvering will often require a small steering radius provided by steerable tires, skid-steer track, and articulated bodies, plus more traction force to account for

FIGURE 1-21 A common type of forest harvesting machine is a feller-buncher. It cuts and stacks tree trunks. These machines commonly use self-leveling cabs to operate on steeply sloped hill faces.

steering resistances. If the distance between two obstacles is less than two vehicle lengths, it's best to adopt articulated steering. If obstacles such as boulders, stumps, or mounds of material are encountered, it's important that no interference between the obstacle and the bottom profile of the machine takes place that could cause a "hang-up" for a machine. Off-road vehicles may need to move at slow speeds through creeks or shallow ponds. Equipment should be designed to prevent water from entering or damaging any component of the vehicle.

Driver visibility—several types of visibility are taken into account during vehicle design. Primary visibility refers to the operator's ability to see outside the cab in any direction, both near and far. Secondary visibility refers to how well the driver can monitor instruments and controls in the workplace and cab. Recognition distance or the distance a driver needs to recognize objects determines the maximum safe machine travel

FIGURE I-22 The engine operating cycle of a backhoe loader.

speed. Having a long recognition distance means lines of site and machine layout is particularly important for machines that travel fast. How fast a vehicle travels in turn influences the type and capacity of the braking system. Larger brakes with more safety features are needed by fast machines.

Engines—each off-road equipment application presents different mechanical and duty-cycle demands on the diesel engine (**FIGURE I-22**). This variety of mechanical demands in turn requires a wide range of engines configured to power each different type of equipment. Engines will range in power from just 10 hp to thousands of horsepower. For example, Caterpillar's smallest mini-excavator weighs just over 1 ton at 2,060 lb (930 kg) and uses a 13 hp diesel engine. In contrast, Cat's largest model, the CAT 6090, which weighs in excess of 2,160,510 lb or 1,080 tons (979,990 kg), has a 4,500 hp engine and a bucket as large as 52.0 m³. Operating requirements of off-road equipment mean these engines endure a more strenuous set of demands and duty cycles than on-highway equipment. For example, off-road equipment depends on its engines not only to propel the vehicle but to operate attachments like buckets, blades, and shovels. A backhoe may use the same engine as an electric generator, but the generator is used for extended periods at constant speeds and loads. In the loader, the duty cycle features frequent cycling between high engine speeds and loads, plus extended low-speed idling between tasks. Off-road vehicle propulsion requires an engine that's capable providing traction over a wide range of terrain profiles and physical conditions. Most off-road machines also use engine-driven hydraulic pumps to power the attachments in order to accomplish a specific task. These additional accessories create additional unique power demands on the engine that are not found in on-highway engines, where power is primarily used for propulsion.

Diesel engines are the workhorse for most of the off-road machines around the world. In 2003 in North America, diesel accounted for 67% of the engines used on farms, 100% of engines in construction, and 72% of engines in mining. In spite of the higher acquisition cost, diesel engines are used more often because they have the following advantages:

- higher torque output at lower engine speeds (**FIGURE I-23**);
- superior fuel economy—smaller diesels will have 25–40% better fuel economy than spark-ignited engines, but larger

turbocharged engines can achieve fuel efficiency more than 10 times that of spark-ignition engines;

- greater durability—in small to mid-range sizes, diesels will last 3–5 times longer than spark-ignition engines, sometimes lasting in tractors and bulldozers for as long as 20 to 30 years, and lasting for longer than 50 years in rail locomotives with engine speeds topping out at 110 rpm.

To lower fuel costs and reduce emissions, hybrid powertrains are frequently used. Hybrid off-road equipment creates synergies between hydraulics, engines, batteries, and electric motors. Flywheel and hydraulic-energy storage systems can produce more power with lower emissions and smaller engines while using significantly less fuel. One example is Caterpillar's D7E, a dozer that has a diesel-over-electric drivetrain. Advertised fuel savings of 10–30% are achieved, and some customers report even higher numbers. John Deere claims that its hybrid wheel loader gets 25% better fuel economy, while Komatsu has a hybrid excavator achieving 25–41% improved fuel efficiency. The hydraulic hybrid-design stores braking energy, and fluid

FIGURE I-23 Diesel engines are used in almost all off-road diesel applications, primarily because they produce more power while burning less fuel than spark-ignition engines.

FIGURE I-24 Emission standards for off-road diesel engines are organized into tiers. The level of permissible emissions and when the engines must meet targets for emission reduction depend on engine power output.

energy returning to the reservoir from cylinders retracting under the force of gravity or loads in hydraulic accumulators, which is used to accelerate the machine in subsequent machine cycles.

The use of gaseous fuels such as propane and natural gas is typically found in warehouse material-handling equipment like power lift or forklift machines. Low emissions from these engines compared to gasoline or diesel fuels is the primary reason for using these fuels. Acquisition costs are lower for equipment using engines based on popular spark-ignition, gasoline fuel designs. While not without hazards, gaseous fuels are stored and handled more safely and easily, compared to gasoline.

Engine Emission Standards

Since off-road diesel equipment covers a very wide variety of engines used in many different applications, emission standards harmonized around the world group engines into emission categories depending on power output. Emission standards are phased in depending on the engine horsepower and schedules, called “tiers.” Tier 4 standards regulate the latest engines. The emission standards regulate nitrogen oxides (NO_x), hydrocarbons (HC) or non-methane hydrocarbons (NMHC), carbon monoxide (CO), and particulate matter (PM), which is made up of mostly black soot (**FIGURE I-24**).

Ergonomic Cab Design

Ergonomics refers to the study of human movement factors applied to workplace design to improve worker productivity while reducing the likelihood of injuries, such as repetitive strain. As mentioned earlier, the operator’s cab is a workplace, and so functional considerations for the operators comfort and access to controls in the design of the cab are important to a machine’s productivity. The operator’s visibility, easy access to all controls, and safety are important for the operator to operate the machine at peak performance and productivity. Proper clearances between the operator and the machine components are necessary to provide access to and from the workplace. The

Society of Automotive Engineers (SAE) outlines criteria for cab access systems in order to help minimize accidents and injuries to workers getting on or off or moving about while servicing or preparing to operate off-road machines (**FIGURE I-25**).

FIGURE I-25 The presence and location of items such as grab handles and steps are important to minimize the probability of accidents for workers getting on and off the machine.

Information for dimensions and locations for steps, handrails, and handholds are included in the criteria.

Dimensions between the seat, instrument cluster, levers, and pedals are important for ease in manipulating operating controls. The SAE has developed a document called the “Recommended Practice, Instrument Face Design and Location for Construction and Industrial Equipment.” The standard recommends grouping instruments:

- Group similar function instruments or controls on the panel.
- Make related groups of instruments equal in size.
- Design the panel as symmetrically as possible.
- Provide a central zone on the panel for the highest priority instruments. This is the arc lying within the 30° cone for easy eye movement, which is 380 mm wide at 700 mm from the operator's eye.
- Group the gauges in the priority zone horizontally and according to function with engine gauges to the left of the panel center and transmission gauges to the right. The panel center should be over the steering column or located around the tachometer or by a group of indicator lights.
- All remaining instruments should appear on either side of the priority group and keep their relative positions the same on all vehicles in the line.
- Controls on the instrument panel should also follow a standard for the whole line of vehicles. Universal symbols for operator controls have been standardized to achieve proper association between controls and displays.

Other industry standards for controls include the following:

When a foot-pedal control operates a clutch, it is actuated by the operator's left foot with the direction of motion forward and/or downward for disengagement.

Continuously used primary hand controls such as hand throttles, shift levers, and other control lever in tractors should be assigned to the right hand, and the left hand should remain available for steering at all times (FIGURE I-26).

The engine speed hand-operated control should be located to operate with the right hand.

Rocker and toggle switch movements shall be consistent with the movement of a control lever used to control a similar function.

When a hand control lever is used for lift controls, implements, or equipment, the direction of motion is generally forward, downward, or away from the operator to lower the implement or equipment and rearward, upward, or toward the operator to raise the implement or equipment.

Note that there are two different standards used in excavators to control the boom and bucket, plus the direction of cab swing. The SAE standards (American) and International Standards Organization (European) both spread the four main digging controls between two x-y joysticks, with each standard using different forward and side movements controlling the boom and dipper cylinders in opposite directions. The x-y configuration enables an operator to control all four functions simultaneously. Switches are commonly used by electronically controlled joysticks to allow operators to select which control configuration they prefer to use (FIGURE I-27).

Less frequently used controls such as those for power take-offs (PTO), clutch, parking brake, and differential lock should be designated for left-hand or left-foot operation.

- Use of color-coded hand controls are intended to help operators identify various types of controls. Red is used only for single-function engine stop controls (FIGURE I-28).
- Orange is used only for machine ground motion controls, such as engine speed controls, transmission controls, parking brakes or park-locks, and independent emergency brakes.

FIGURE I-26 Comparing the cab control layout for a dozer with hydrostatic drive propulsion and one using clutches and brakes to control track differential speeds for propulsion and turning.

FIGURE I-27 Joysticks in an excavator control the movement of the digging function and cab swing.

FIGURE I-28 The use of universal symbols and color-coded controls in the instrument cluster of a backhoe loader.

- Yellow is used only for function controls that involve the engagement of mechanisms, such as power take-offs.
- Black or some other dark color is used for all controls that have positioning and adjusting functions, such as steering, hydraulic control, implement hitch, seat adjustment, and machine lighting.

Off-road vehicles require lighting systems that allow safe operation during nighttime operation. For example, in agriculture there is a standard titled “Lighting and Marking of Agricultural Equipment on Highways” that specifies lighting and marking of equipment whenever it’s operated or is traveling on a highway.

► What Does a Heavy Equipment Repair Technician Do?

K01004

Over the past decade, the heavy equipment industry, including construction equipment such as the backhoes, bulldozers, cranes, excavators, wheel loaders, graders, and forklifts, has achieved a nearly 6% annual growth rate worldwide. Construction of new transportation infrastructure, resource extraction, housing construction, and the refurbishing of older buildings has driven much of this industry growth. The spinoff is more jobs for heavy equipment technicians.

Job Description

Heavy equipment repair technicians install, maintain, and service off-road vehicles and equipment designed to accomplish a wide variety of tasks, such as transporting objects, lifting, plowing, drilling, and cutting. They may also be required to operate heavy equipment as part of diagnostic strategies outlined by a manufacturer. During maintenance and repair procedures, technicians test and adjust equipment; repair or replace defective parts, components, or systems; and diagnose faults or equipment malfunctions. They will also validate the correct operation of machinery, disassemble and reassemble heavy equipment and its components, order new parts and conduct inspections on machinery to ensure that it is properly functioning and complies with legislated safety or manufacturer standards. Technicians need to have the ability to write service reports, read and comprehend information in technical manuals, and interpret technical drawings of such things as schematics of electrical or hydraulic circuits.

Training of HD equipment technicians at vocational schools, colleges, and universities is aimed at producing competent technicians in a shorter time period than simply developing skills through practical experience alone could accomplish. To develop the best problem-solving skills, safe work practices, and repair techniques, vocational colleges concentrate on teaching principles of the construction, function, and operation of mobile off-road heavy equipment systems. Principles of science applicable to each subject and area of study supplement basic instruction, which are timelessly essential when analyzing problems and developing maintenance and repair techniques or strategies.

HD Equipment Technician Licensing

Unlike the repair industry for on-road vehicles, there isn’t a mandatory or standardized certification that heavy equipment repair technicians are required to possess in every state

or province. Instead, college diplomas, associate degrees, and certificates are available. Employers prefer individuals who have some understanding or background in mechanics and who are familiar with subject areas such as electrical systems, diesel engines, hydraulics, powertrains, brakes, and steering systems. In associate degree programs, students undertake a broad curriculum emphasizing mathematics, applied sciences, communications, marketing, logistics, industrial safety, law, and writing. Manufacturers also offer training programs, often in association with community colleges. While technician licensing is not mandatory, some equipment may need to be moved or operated during the service or repair process, which requires an operator's license. A further advantage for technicians is to hold a commercial vehicle driver license in addition to a regular driver's license, to operate truck trailer combinations when equipment is floated between a job and repair site.

New technologies to increase driver safety, comfort, machine productivity, and reliability are placing ever-increasing demands for greater technician skills. Technological advancements, including air-conditioned cabs, hydrostatic drives, automated transmissions, telematics, engine monitoring systems, and GPS guidance systems used by autonomous and semi-autonomous driverless machines systems, require new skill sets and knowledge. Industry growth, combined with the increased features, demands more technicians with greater skills and training in heavy equipment.

Where Do Technicians Work?

Heavy-duty equipment technicians are employed by companies that own and operate heavy equipment, heavy equipment dealerships, rental and service companies, construction contractors, forestry companies, mining companies, ski hills, and government departments that service and repair their own equipment. Technicians will also work in marine, oil and gas, material-handling, landscaping, and land-clearing industries. Many HD equipment technicians develop a wide range of skills and knowledge on a vast variety of equipment types and manufacturers.

In terms of working conditions, HD equipment technicians work in the full range of environmental conditions, including dealer repair centers, component rebuild shops service and shops owned by industry contractors. While one can expect to work primarily in well illuminated, ventilated, safe, clean shops with the latest service equipment, training, and service information systems, it is common to perform onsite equipment repairs. Since it is not always practical or possible to tow disabled equipment back to a shop, technicians should expect to work for long days at remote sites during inclement weather conditions. For example, in Canada in cold weather, broken down equipment

is tented over during servicing. This may take place on the side of a steep hill, in a forest while repairing logging equipment, or alongside a busy right of way for a pipeline. In those situations, a technician will transport their entire toolbox and a large supply of parts potentially needed to repair a machine. Repairing track equipment may require digging and shoring up equipment with timbers to access the undercarriage for repairs.

A positive attitude toward adverse working conditions in the field is essential at times. Since work often requires standing, bending, crawling, lifting, climbing, pulling, and stretching, it's important for technicians to be in and maintain a good physical condition. The use of other senses, such as smell, hearing, and vision, are important when performing diagnostic work. While many people believe that because heavy equipment is large and heavy, proportionally more strength is required to complete tasks. This idea is not entirely correct. Heavier components and larger fasteners require different working techniques using specialized assistance from small cranes; hydraulic presses; larger, more powerful air tools; and even other equipment such as backhoes and forklifts. More often than not, the ability of technicians to develop a repertoire of creative or clever work techniques and employ a variety of power devices to overcome unique challenges working on heavy equipment is better and more often deployed by a skilled technician than simply using brute strength.

The size and complexity of off-road heavy equipment increases the potential for injury and threats to life and limb. For this reason, safe working practices critical. Technicians must be conscious of potential impact of their work on people, equipment, the work area, and environment. In recent years, greater emphasis is placed on the safe handling, disposal, storage, and recycling of toxic or environmentally hazardous materials such as coolant, oil, used filters, batteries, refrigerants, and dust from diesel particulate filters.

Technicians also need to possess the ability to work alone or as part of a team. There are often problems requiring collaboration between fellow technicians to solve or help perform physical tasks. The work many heavy-duty technicians perform presents some of the toughest challenges of any trade. The complexity and sophistication of many types of heavy equipment, particularly problems with contemporary hydraulic systems, place additional demands on the ability to think logically, methodically, and quickly. Given the cost of parts and the loss of production time that can run into thousands of dollars and hours, a dependable level of skill and competency is demanded from the best HD technicians. It's not surprising to find technicians with those rare combinations of skills to receive compensation commensurate with those abilities earning well above a six-figure annual income.

► Wrap-Up

Ready for Review

- ▶ Off-road equipment sales are undergoing steady growth, which will provide employment opportunities and demand and for new skills in the future.
- ▶ Off-road mobile equipment is defined as a machine having attached components, designed to work in an off-road environment or designed to operate at low speeds.
- ▶ Off-road machines have an unloaded vehicle speed that can't exceed 45 mph, and there should be no capacity to carry occupants other than the driver and operating crew.
- ▶ Most off-road equipment uses fluid power systems, which use either air or hydraulic force, to operate equipment attached to the vehicle.
- ▶ Off-road propulsion systems are unique and specially adapted to the operating terrain and other ground conditions where they are used. The systems provide extra traction over soft, uneven terrain while often performing heavy work.
- ▶ The major source of energy for propulsion on a machine is called the prime mover. Engines and electric motors are most often used as prime movers.
- ▶ Not only does the prime mover provide power to move the machines around off-road worksites, but it also operates cables and fluid power systems performing specialized jobs.
- ▶ Tracked machines, also called track undercarriage machines, use either steel plates or rubber belts that have the advantage of providing lower ground pressure for heavy machines to prevent them from sinking.
- ▶ Tracked machines provide additional traction force through cleat-like features on track shoes called grousers.
- ▶ The Caterpillar Company was cofounded by Benjamin Holt, who acquired the patents for the track-type undercarriage. The name Caterpillar was used to describe the machinery using track-type undercarriage.
- ▶ The first use of wider pneumatic tires on off-road equipment took place in the 1930s, and aircraft tires were first installed on an agricultural tractor.
- ▶ The use of extra weight for tire ballast to make a tire heavier adds stability, helps prevent machine tip-over, and increases traction force applied to the ground by the tire.
- ▶ The use of hydraulic fluid power on off-road equipment eliminated the use of cable systems on machines which simplified machine control operation.
- ▶ Hydraulically operated equipment meant that equipment could be operated much more simply, faster, and with greater force.
- ▶ The use of hydraulics enabled machines to force shovels and buckets into the ground rather than rely on the weight of gravity. Hydraulic attachments could be added to machines.
- ▶ Increasing equipment productivity drives machine design. Productivity is improved by increasing the load-carrying capacity and/or shortening the cycle time. Cycle time can be shortened by increasing machine travel or operational speed.
- ▶ Diesel engines are traditionally the preferred prime mover because they produce more power and use less fuel than other engines. Diesel engines also have greater durability.
- ▶ Emission standards for off-road equipment are established by horsepower ratings.
- ▶ To improve productivity and safety, machine cabs and controls use ergonomic designs with universal symbols and color coding on switches and controls. Cabs also have roll over protection for operators.

Key Terms

ballast The addition of weight inside a pneumatic tire that's used to give the machine additional stability and traction force. A common ballast material is a water and calcium chloride mixture.

differential steering or **skid steering** A steering principle where one track will turn at a different speed than the other, providing even the largest track-type machines with exceptional maneuverability.

fluid power Both air and hydraulic systems transfer power to machine implements and accessories performing work.

ground pressure The force measured in pounds per square inch (psi) a machine applies to the ground through its contact patch with a track or tire.

grouser A bar or cleat-like protrusion from a track shoe of a track-type undercarriage.

hydrodynamic A system that converts kinetic energy contained in hydraulic fluid flow into mechanical movement.

hydrostatic The transfer of hydraulic fluid energy from flow and pressure.

operating cycle The time that a machine requires to perform a specific operation such as fill and dump one bucket of material.

prime mover A technical term describing the principle device used to produce mechanical energy in off-road equipment, propelling the machine and supplying specialized equipment attachments.

productivity A measurement of machine power. Productivity is calculated by measuring the amount of work performed by a machine and dividing that by the time it takes to perform the work. Units for productivity vary and could range from tons of material moved per hour or how many trees are moved a minute.

track shoes Metal plates linked together to form the tracks of a track-type undercarriage system.

undercarriage The generic name given to all the components making up the propulsion mechanism for track drive equipment.

Review Questions

- Which of the following machines is expected to have the highest sales growth in 2019?
 - Bulldozers
 - Asphalt equipment
 - Forklifts
 - Loaders
- Telematics refers to
 - wireless transmission of machine fault codes.
 - monitoring and control machine operations from a distance.
 - self-steering equipment.
 - GPS navigation.
- Which of the following defines the features that classify off-road equipment?
 - The Society of Automotive Engineers (SAE)
 - The Code of the Federal Registry (CFR)
 - The Environmental Protection Agency (EPA)
 - The Equipment Manufacturers Association (EMA)
- Which of the following best defines a hydrostatic drive system?
 - Transmission of energy through flow and pressure
 - Transmission of energy through fluid flow only
 - The use of hydraulics motors in machinery
 - The use of hydraulic pumps in machinery
- Ground pressure refers best to which of the following?
 - Downward force exerted by tires
 - The weight per unit area or pounds per square inch (psi) exerted by machine track
 - How soft or complaint a ground surface is
 - The hardness of ground beneath track
- The first use of track undercarriage anywhere was for a
 - farm tractor.
 - grader.
 - excavator.
 - log hauler.
- Which of the following ground conditions is track-type undercarriage best suited for?
 - Grass-covered fields
 - Snow plow operations
 - Mining
 - Soft, loose sand, soil, or gravel
- Tire ballast is designed to
 - extend tire life.
 - increase traction force and machine stability.
 - seal tires to prevent leakage.
 - freeze when the temperature gets cold.
- How is machine productivity best measured?
 - Over an operating cycle
 - The amount of time it takes to perform a task
 - The amount of load a machine can carry
 - By using a stopwatch
- Which off-road emission tier would include the latest diesel engines?
 - Tier 1
 - Tier 3

- Tier 4
- Tier 5

ASE Technician A/Technician B Style Questions

- Technician A says that diesel engines are most commonly used by off-road machines since they have fewer maintenance requirements, such as the need to change spark plugs. Technician B says that diesel engines are used since they provide more power and use less fuel. Who is correct?
 - Technician A
 - Technician B
 - Both Technician A and Technician B
 - Neither Technician A nor Technician B
- Technician A says hybrid off-road equipment is used to reduce fuel consumption. Technician B says that hybrids have reduced engine emissions. Who is correct?
 - Technician A
 - Technician B
 - Both Technician A and Technician B
 - Neither Technician A nor Technician B
- Technician A says that the color red is used to designate engine shut-down controls. Technician B says yellow is used to identify an engine shut-down control. Who is correct?
 - Technician A
 - Technician B
 - Both Technician A and Technician B
 - Neither Technician A nor Technician B
- Technician A says that excavators use joysticks with a standardized x-y pattern of control to rotate the operators cab and manipulate the bucket. Technician B says that joysticks can be configured to move the cab and bucket in one of two ways. Who is correct?
 - Technician A
 - Technician B
 - Both Technician A and Technician B
 - Neither Technician A nor Technician B
- Technician A says that cable-operated equipment was replaced using hydraulic controls. Technician B says hydraulic systems replaced pneumatic systems on early equipment. Who is correct?
 - Technician A
 - Technician B
 - Both Technician A and Technician B
 - Neither Technician A nor Technician B
- Technician A says that a hydraulic motor will weigh less than an electric motor. Technician B says that hydraulic control systems are smoother than pneumatic control systems because they can better absorb shock loading. Who is correct?
 - Technician A
 - Technician B
 - Both Technician A and Technician B
 - Neither Technician A nor Technician B

7. Technician A says that track drive systems were first invented and used in England. Technician B says that the Caterpillar Company invented track drive undercarriage. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says that one thing that all off-road equipment has in common is the use of hydraulic or air attachments used to perform a specialized task. Technician B says that all off-road equipment will have engines and an axle able to carry over 29,000 lb. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
9. Technician A says that track drive machinery with differential steering is the most maneuverable steering system. Technician B says that machines with tires are better able to navigate around obstacles. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
10. Technician A says that only diesel engine is considered to be a prime mover. Technician B says the electric motors and hydrostatic drives are prime movers. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

CHAPTER 2

Identification & Classifications of MORE

Knowledge Objectives

After reading this chapter, you will be able to:

- **K02001** Categorize MORE according to operation, drive system, and function.
- **K02002** Describe construction features of various categories of MORE.
- **K02003** Explain terminology associated with the construction and operation of MORE.
- **K02004** Describe MORE attachments.
- **K02005** Identify common steering, propulsion, frame, and hydraulic systems and components.

Industry/Accreditation

After reading this chapter, you will be able to:

- **I02001** Communicate trade-related information using standard terms for components and operations.

Skills Objectives

After reading this chapter, you will be able to:

- **S02001** Start, operate, and shut down equipment.

Attitude Objectives

After reading this chapter, you will be able to:

- **A02001** Acquire correct service information for repair and maintenance procedures.

► Introduction

Anyone passing by a major construction project has no doubt witnessed many types and sizes of mobile off-road equipment (MORE) in use. Practically any construction-related need imaginable can be satisfied with some type of MORE. In addition to construction, other industries, such as forestry, mining, and agriculture, also benefit from the use of such heavy equipment. Some pieces of heavy equipment, such as a compactor, are designed for one specific purpose. Other types of equipment, such as an excavator, might be used for several different tasks. Additionally, many types of MORE can be fitted with attachments to further enhance the equipment's capabilities.

For service technicians to work safely and effectively on MORE, they must be familiar with the basic categories of equipment and understand what each type is used for. They also must recognize common features of MORE and understand how these machines are powered and operated. This chapter will identify basic MORE classifications and examine construction features found in these types of equipment. It also will describe common attachments, systems, and components associated with MORE and explain terminology pertaining to the construction and operation of the equipment.

► Basic Categories of MORE

K02001

MORE classifications can be based on different criteria. For example, equipment manufacturers might categorize their products according to the industry they serve, such as agriculture, forestry, or construction. Another classification method is based on the general purpose or function of the equipment. With this method, material-handling equipment would include machines such as cranes, forklifts, and knuckleboom loaders. The way equipment is propelled, or driven, is another method of classifying MORE. For example, track-mounted equipment would use metal or rubber crawler tracks to provide locomotion and include equipment such as dozers, excavators, and some types of cranes. Wheel-mounted equipment would use wheels or tires for mobility and include equipment such as loaders, graders, and haulers. Regardless of the classification method used, the same equipment will often fit into different categories. The equipment covered in this chapter is categorized by its use in excavation, earth moving and mining, grading and compacting, and hoisting and handling.

SAFETY TIP

Service technicians working at practically any work site are likely to encounter numerous types of MORE being operated at the same time. For this reason, technicians must be aware of the inherent hazards of working around heavy equipment and people. They must remain vigilant at all times to avoid accidents that could kill or injure themselves or other personnel or damage equipment.

Excavation Equipment

The Occupational Safety and Health Administration (OSHA) defines excavation as “Any man-made cut, cavity, trench, or depression in an earth surface formed by earth removal.” Based on this definition, many organizations include mass excavation equipment such as excavators, backhoes, and trenchers in this category of MORE.

Excavators

An excavator is a piece of heavy equipment that is commonly used in earth-moving, trenching, and loading applications (**FIGURE 2-1**). It has a large **gooseneck boom** and bucket on the front of the machine that are mounted with an operator's cab onto a rotating platform. The platform, which can be rotated a full 360 degrees to enable the operator to swing the boom and bucket in any direction, is attached to an **undercarriage** that has crawler tracks or wheels that allow the excavator to be moved.

FIGURE 2-1 Typical excavator.

You Are the Mobile Heavy Equipment Technician

A customer calls and asks if you can come out to a construction site to check over an excavator that they are going to use for some demolition work. The customer says they haven't used this particular excavator in a while and wants you to check it over before they start the job to avoid any unnecessary downtime.

1. Why would you need to ask about the basic type of excavator?
2. Why would you need to ask about any special attachments being used on the equipment?
3. Would it be important to ask about the basic propulsion and control systems? If so, why?
4. Should you ask about any manufacturer's manuals for the equipment? If so, why?

FIGURE 2-2 Common track-mounted excavator applications: **A.** backfilling, **B.** lifting, **C.** trenching, and **D.** loading.

Two basic types of excavators are standard hydraulic excavators: track-mounted machines with crawler tracks and wheel-mounted excavators, which use rubber tires. Standard hydraulic excavators (usually just called excavators) have excellent stability and traction. They are available in many sizes and capacities, from mini excavators with engines of less than 20 hp (15 kW) to extremely large excavators with engines of several hundred hp (kW). Track-mounted excavators have several common uses (**FIGURE 2-2**).

Wheel-mounted excavators can perform the same basic jobs as track-mounted excavators. The major difference between the two is that a wheel-mounted excavator has axles with rubber tires instead of crawler tracks (**FIGURE 2-3**). Rubber tires are more suitable for operating on pavement or other surfaces that need to be protected.

Both track-mounted and wheel-mounted excavators are available as **telescoping boom** excavators (**FIGURE 2-4**). In other words, instead of using the common gooseneck boom and bucket arrangement, these excavators use a telescoping boom that can

FIGURE 2-3 Wheel-mounted excavator.

FIGURE 2-4 Telescoping boom excavator:

be extended outward and retracted. Telescoping boom excavators are commonly used in sloping and finish grading applications.

Backhoe Loaders

K02001

A popular piece of MORE that is similar to an excavator is a backhoe loader (**FIGURE 2-5**). In a typical configuration, a hydraulically operated excavating arm is mounted onto the rear of a rubber-tired tractor or, in some cases, a crawler (track-mounted) tractor. The backhoe part of the equipment is commonly used for small excavation work, digging manholes, and trenching. A loader bucket is attached to the front of the tractor. The front-end loader is often used for removing excavated soil, backfilling, and loading trucks. The tractor engine provides the power for the backhoe and the loader and enables the tractor to be maneuvered.

While backhoe loaders come in many sizes and models, they are generally smaller and less powerful than other types of excavating equipment. The boom has less swing than that of an excavator, but the backhoe's mobility and maneuverability make it a very useful piece of excavation equipment—especially in applications where larger excavators cannot be used.

FIGURE 2-5 Typical backhoe loader:

Trenchers

As its name suggests, a trencher is a type of MORE that is used to dig trenches for burying pipes, cables, culverts, and similar items. Many different types of trenchers are available, from small tractor-mounted versions to large track-mounted models. One common type of trencher called a **chain trencher** (**FIGURE 2-6**). It is a track-mounted trencher with a hydraulically controlled boom that can be lifted and lowered to control the depth of the trench. A chain with cutting bits travels around the boom to cut through hard soil and rock. Chains of different widths are available to cut narrow or wide trenches.

Another type of trencher is a **wheel trencher** (**FIGURE 2-7**). Instead of using a boom and cutting chain, a wheel trencher uses a wheel with teeth to dig through pavement or hard soil. Wheel trenchers come in many sizes, from small portable models like the one shown in Figure 2-7 to large track-mounted trenchers capable of cutting a trench 36 inches (91 cm) wide and up to 7 feet (2.15 m) deep.

Tractor-mounted trenchers are commonly used for burying utility lines at construction sites (**FIGURE 2-8**). In this application, a tractor pulls the trencher blade attachment to lay the cable.

FIGURE 2-6 Track-mounted chain trencher:

FIGURE 2-7 Portable wheel trencher:

FIGURE 2-8 Tractor-mounted trencher.

Earth-Moving and Mining Equipment

Most of the MORE used for earth moving and mining is designed to move large amounts of soil or aggregate from one place to another. Typically, these pieces of equipment include dozers, loaders, and off-road dump trucks.

Dozers

A dozer, or bulldozer, is one of the most common pieces of MORE used in earth-moving and grading applications. The

FIGURE 2-9 Typical dozer.

primary purpose of a dozer is to push large amounts of soil, aggregate, or other material. A typical dozer (FIGURE 2-9) is an extremely heavy piece of equipment that moves on crawler tracks and has a wide blade mounted on the front. The blade is controlled hydraulically, and it can typically be raised, lowered, angled, and tilted to accommodate specific needs.

As with most types of MORE, dozers come in a variety of sizes and models. Four basic types of dozers are shown in FIGURE 2-10: low-track dozers, which are commonly used for

FIGURE 2-10 Basic types of dozers: **A.** low-track crawler dozer; **B.** high-track crawler dozer; **C.** high-speed dozer; and **D.** wheel dozer with compactor wheels.

grading purposes; high-track dozers, which are typically used for pushing large amounts of material; high-speed dozers, which are known for their agility and speed during finish grading jobs; and wheel dozers, which have a steering wheel and operator controls similar to those of a truck.

Loaders

A loader is a type of MORE that has a large bucket mounted on the front of a machine that looks much like a dozer. However, while a dozer blade is designed to push material, a loader bucket is designed to be raised, lowered, and tilted so that it can scoop up material, transport it to a different area on the site, and dump it. One of the benefits of a loader is that the lifting arms for the bucket can lift the bucket high enough to dump material onto piles or into trucks.

Loaders come in many sizes and configurations. They can be track-mounted or wheel-mounted (**FIGURE 2-11**).

Another type of loader that is popular for small jobs, especially jobs in tight spaces, is a skid steer loader (**FIGURE 2-12**). Skid steer loaders typically have a relatively small diesel engine, a hydrostatic drive system, and a bucket. They are available as track-mounted or wheel-mounted machines, and they have a very small turning radius. Modern skid steer loaders have

FIGURE 2-12 Skid steer loader.

joysticks in the cab that enable an operator to control the loader movement and the bucket.

Off-Road Dump Trucks

Off-road dump trucks have the same fundamental purpose of any dump truck—to safely move large amounts of material from one place to another (**FIGURE 2-13**). However, the similarities end there. Off-road dump trucks are unlike any dump truck that is seen on the highway. In fact, because of their massive size, these trucks are prohibited from operating on a highway. Instead, they are rugged, heavy-duty machines built to withstand the challenging conditions of road-building, construction, and mining sites. Off-road trucks are loaded using various types of loaders or excavators. They are then driven to another area on the site where the truck's powerful hoist cylinders lift the body and dump the load.

SAFETY TIP

Operators have a very limited view from the cab of a haul truck. Any personnel or equipment must be a considerable distance away from the cab to be visible. Always use care when approaching or working around haul trucks.

FIGURE 2-11 Common types of loaders: **A.** track-mounted loader and **B.** wheel-mounted loader.

FIGURE 2-13 Off-road dump trucks.

► TECHNICIAN TIP

Operating an off-road dump truck requires special training and certification. Off-road trucks are vastly different from highway vehicles. Never attempt to operate any type of off-road truck without first completing the proper training.

Off-road trucks are usually divided into two basic types: **rigid-frame** trucks and **articulated-frame** trucks. A rigid-frame truck, which is sometimes called a rigid dump truck, a haul truck, or a mining truck, has a non-pivoting frame that supports the cab and the body (**FIGURE 2-14**). A typical rigid-frame truck has two axles—a front axle for steering the truck and a rear axle for transferring the engine's power to the wheels. Because of the massive amount of weight that a haul truck can carry and its need for stability, the rear axle usually has dual wheels on each side.

Rigid-frame trucks use large, powerful diesel engines with as much as 4,000 hp (2,983 kW) or more. Some of the largest rigid-frame trucks also have electric motors inside the axle at the rear wheels. In these trucks, the diesel engine drives an AC (alternating current) alternator or DC (direct current) generator that, in turn, powers the electric motors. This powertrain setup provides additional power to each drive wheel and helps with braking.

Articulated-frame dump trucks, or articulated haulers as they are often called, are typically smaller than rigid-frame trucks (**FIGURE 2-15**). They are designed more for maneuverability in rough terrain than for sheer hauling capacity. However, articulated-frame trucks are still large pieces of MORE. These trucks can have engines with over 600 hp (447 kW) and bodies that can haul over 60 tons (54 tonnes).

An articulated hauler has a permanent hinge, or pivoting point, in the frame. The pivoting point is located between the operator's cab and the dump body so that all of the hauler's wheels follow the same path. Most articulated-frame trucks have all-wheel drive with a front axle for steering and two rear axles for driving the vehicle. The steering and drive systems are controlled hydraulically.

FIGURE 2-14 Rigid-frame truck.

FIGURE 2-15 Articulated-frame truck.

FIGURE 2-16 Underground mining truck.

In mining applications, special articulated-frame trucks are used underground. The underground mining truck is much like an aboveground truck, but with a lower clearance (**FIGURE 2-16**). The height reduction is achieved by moving the operator's cab forward of the front axle. Most underground mining trucks have all-wheel drive and two axles (one front-steering axle and one rear axle). Their capacities are similar to aboveground articulated-frame trucks.

Grading and Compacting Equipment

Before roads can be paved or buildings and structures can be erected, it is necessary to establish a solid foundation of soil. This is often accomplished by using scrapers to move and disperse soil, graders to smooth the soil and create slopes and ditches, and compacters to pack the soil and create a firm surface.

Scrapers

A scraper is a type of MORE that is used to move large amounts of soil or aggregate from one place to another. While some smaller scrapers are towed behind a dozer or tractor, most large

FIGURE 2-17 Wheeled tractor scraper.

ones are self-propelled, rubber-tired models (**FIGURE 2-17**). These scrapers are commonly called wheel tractor scrapers.

An operator drives the scraper forward and uses the hydraulic controls in the cab to lower the scraping edge and the hopper, or bowl. The soil is scraped into the hopper. Once the hopper is full, it is raised and closed. The scraper is then driven to an area where the back of the hopper is opened, and the soil is dumped and dispersed.

Graders

A motor grader is a long, narrow piece of MORE that has rubber tires, a large diesel engine, and an adjustable blade that is used in many earth-moving, ditching, grading, and smoothing applications (**FIGURE 2-18**). Graders are operated hydraulically with power provided by engines that range from as little as 125 hp (93 kW) to well over 500 hp (373 kW). The blade length on a grader can range from about 12 ft (366 cm) to more than 24 ft (732 cm).

Two basic types of motor graders are rigid-frame graders and articulated-frame graders. Rigid-frame graders are typically

FIGURE 2-18 Typical motor grader.

FIGURE 2-19 Motor grader controls are very sophisticated today featuring GPS guidance.

smaller and older graders that have a single frame along the length of the machine. Most graders today are articulated-frame graders that have a pivoting point in the frame. The pivoting frame enables the grader to work at an offset angle. In other words, the part of the grader to the front of the pivot can travel along a different line than the section to the rear of the pivot. This feature improves the grader's maneuverability and makes it easier for the grader to perform certain tasks, such as cleaning out ditches. Grader controls these days are very sophisticated using GPS positioning for blade height and angle **FIGURE 2-19** shows a modern motor grader with GPS control.

Compactors

Whenever soil is graded and dispersed over an area, it must be compacted before any type of structure is built on it or any type of pavement is applied to it. If the soil is not compacted, it will settle on its own over time. However, any structure or pavement that is placed over that soil will be unstable and crack. Compactors are types of MORE used to compact soil and speed up the settling process in a consistent manner. In most cases, compactors are self-propelled machines equipped with large rollers or tires that are driven back and forth over soil, gravel, or asphalt to compact the material. Four common types of "ride-on" compactors are steel-wheel rollers, pneumatic tire rollers, vibratory steel-wheel rollers, and sheepfoot rollers (**FIGURE 2-20**). These compactors have a diesel engine and a steering wheel or joysticks for operator control. Some models have an articulated frame for better maneuverability.

Hoisting and Handling Equipment

Hoisting and moving loads is a common requirement at nearly every construction and forestry site. Three types of MORE used for lifting, moving, and loading components and material are cranes, forklifts, and knuckleboom loaders.

FIGURE 2-20 Common types of ride-on compactors: **A.** steel-drum roller; **B.** pneumatic tire roller; **C.** vibratory steel-wheel roller; and **D.** sheepfoot roller.

Cranes

When it comes to lifting and moving loads at a construction site, few machines are more suitable than a crane. Cranes are heavy machines that use a boom, cables, and counterweights to lift and move heavy objects. The boom and the operator's cab are mounted onto a rotating platform that enables the crane to lift and swing a load in any direction. Cranes have powerful diesel engines and are available as track-mounted or wheel-mounted machines. The specific size and type of crane that is used depends on factors such as the weight of the load, the terrain at the site, and the mobility that is needed.

Track-mounted cranes are commonly referred to as crawler cranes (**FIGURE 2-21**). They can be used in many rough terrain applications. Most crawler cranes have joysticks for operator controls and a high-strength **lattice boom** that can be raised and lowered. Intermeshing steel rods give the lattice boom its strength.

Wheel-mounted cranes are also used in challenging off-road conditions. Some wheel-mounted cranes are called rough terrain cranes for that reason. As a general rule, wheel-mounted cranes are mobile and can be operated on highway when required, use a steering wheel for operator control, and

have a telescoping boom instead of a lattice boom. **FIGURE 2-22** shows a heavy wheel-mounted crane.

Forklifts

Forklifts, or lift trucks as they are often called, are used not only in warehouse environments but also on construction sites

FIGURE 2-21 Track-mounted (crawler) crane with lattice boom.

FIGURE 2-22 Wheel-mounted crane with telescoping boom.

FIGURE 2-24 Telehandler forklift with telescoping boom.

FIGURE 2-23 Rough terrain forklift.

to move palletized components, sections of pipe, and similar material from one place to another. A typical MORE forklift is commonly called a rough terrain forklift since it has large rubber tires that enable it to move over terrain that is not suitable for conventional forklifts (**FIGURE 2-23**). These forklifts have a large mast in front of the operator's cab that can be tilted forward and backward and a pair of steel forks that can be raised and lowered to lift, carry, and lower material. A diesel engine is mounted behind the operator's cab, and the vehicle is steered with the rear wheels.

A different version of a forklift that is often used on construction sites is a telehandler (**FIGURE 2-24**). A telehandler has a telescoping boom mounted onto the rear of the vehicle that can be extended and retracted to lift objects to greater heights and distances than a typical forklift.

Knuckleboom Loaders

Knuckleboom loaders are a common sight at logging operations. They look like excavators since they have a gooseneck boom that is mounted with an operator's cab on a rotating platform. However, instead of using a bucket at the end of the

boom, knuckleboom loaders use a type of hydraulically powered claw called a **grapple**. The grapple enables the operator to grab logs and other objects and move them onto piles or logging trucks. Mobile knuckleboom loaders are typically track-mounted machines that can move over the rough terrain found at logging sites (**FIGURE 2-25**).

FIGURE 2-25 Track-mounted knuckleboom loader.

► MORE Construction Features

K02002

Machines found in any particular category of MORE share a lot of common features, even though they are manufactured by different companies around the world. Engines, power-train components, operator controls, and other systems may differ somewhat from machine to machine, but the ultimate use and function of the equipment in that category will be the same.

Excavation Equipment Features

Excavation equipment, which includes machines like excavators and backhoe loaders, is designed to remove soil or other material from one area and place it in another area or into a truck. To accomplish this basic task, excavation equipment must have a powerful engine, a drive system, a steering system, some type of boom (gooseneck or telescoping) and bucket, a hydraulic system to power the boom and bucket, and operator controls to drive the equipment and control the operation of the boom and bucket.

SAFETY TIP

All types of MORE have safety features to protect the operator, the equipment, and other personnel and equipment in the area. Service technicians must be familiar with these safety features and always use them during any inspection and maintenance procedures.

The same major components and features of a standard hydraulic excavator can be found on any track-mounted hydraulic excavator, no matter the manufacturer or the size of the excavator (**FIGURE 2-26**).

Construction features for wheel-mounted excavators are very similar to those of standard hydraulic excavators (**FIGURE 2-27**). The main difference is the method of locomotion—in this case, rubber tires instead of crawler

FIGURE 2-26 Major components of a standard hydraulic excavator.

FIGURE 2-27 Major components of a wheel-mounted excavator.

tracks. Outriggers are used on wheel-mounted excavators for added stability.

As with excavators, backhoe loaders share many common features (**FIGURE 2-28**). In nearly every backhoe loader configuration, there is a front loader bucket that can be raised, lowered, and tilted; rubber tires for 2- or 4-wheel drive operation; outriggers to stabilize the machine; an excavating arm that consists of a boom and a stick; and a bucket mounted at the end of the excavating arm. A diesel engine powers the backhoe loader, and hydraulic controls enable the operator to drive the backhoe loader and operate the backhoe and the front loader.

Trenchers come in two basic forms: chain trenchers and wheel trenchers. Both types can be track-mounted or wheel-mounted machines. On a typical track-mounted chain trencher, the crawler tracks enable the trencher to move over rough terrain. The operator uses hydraulic controls to raise and lower the digging boom to the required depth and activate the rotation of the digging chain. The digging chain with teeth travels around the boom to cut through hard soil and rock. A device

FIGURE 2-28 Major components of a backhoe loader.

FIGURE 2-29 Major components of a chain trencher.

called a **crumber bar** follows the digging chain in the trench to prevent loose soil from collecting (**FIGURE 2-29**).

A wheel trencher shares most of the same basic construction features with the chain trencher. It simply uses a large wheel with teeth instead of a cutting chain to dig the trench.

Earth-Moving and Mining Equipment Features

MORE that is used for earth-moving and mining applications is designed to push, scoop up, and haul large amounts of material from one place to another. Common examples of earth-moving and mining equipment include dozers, loaders, and off-road dump trucks. Looking at each of these three types of equipment reveals common construction features.

A typical track-mounted (crawler) dozer has a heavy, wide blade at the front for pushing material. Hydraulic hoist cylinders are used to lift and lower the blade, and hydraulic blade angle cylinders are used to adjust the angle of the blade. All of the hydraulic controls for steering and operating the dozer are in the operator's cab. And a diesel engine provides the necessary power to drive all the systems (**FIGURE 2-30**).

FIGURE 2-30 Major components of a track-mounted (crawler) dozer.

Although other types of dozers are used regularly to meet specific needs, the basic features are essentially the same. Regardless of the size, manufacturer, and specific type of dozer being used, the primary purpose is still to push material.

Loaders look a lot like dozers, but their basic function is to scoop up material, transport it to a different area, and dump it. For this reason, a typical loader has a very large bucket mounted on the front and rubber tires that enable the machine to be driven around the site. A large diesel engine provides the power needed by the loader, and hydraulic controls inside the operator's cab make it easy for an operator to lift, lower, and tilt the bucket. While loaders can be track-mounted, most are wheel loaders with an articulating frame and a steering wheel for easy maneuvering (**FIGURE 2-31**).

Off-road dump trucks, especially rigid-frame trucks used in construction and mining, are enormous pieces of MORE. Even smaller versions of these trucks are huge. Rigid-frame trucks share many of the same major components (**FIGURE 2-32**). The operator's cab and the body are both attached to the rigid frame. The cab has a roll over protective system (ROPS) and a falling object protective structure (FOPS). Inside the cab are the controls

FIGURE 2-31 Major components of a wheel loader.

FIGURE 2-32 Major components of a rigid-frame truck.

needed to drive the truck and dump the body. Stairs provide access to the platform in front of the operator's cab, and railings surround the platform help to prevent falls. An extended section of the body, called the **canopy**, extends over the cab to protect the cab from falling material during loading and transport. Hydraulic hoist cylinders are used to raise and lower the body. The front axle is used to steer the truck while the rear tandem axle drives the truck.

Grading and Compacting Equipment Features

Grading and compacting equipment is used to move and disperse soil, smooth the soil, create slopes and ditches, and pack the soil firmly before any building or paving takes place. In most cases, these tasks are performed using scrapers, graders, and compactors.

Wheel tractor scrapers are heavy self-propelled machines with rubber tires, a scraping edge that can be raised and lowered hydraulically by the operator, and a large hopper (bowl) to collect the material scraped from the ground (**FIGURE 2-33**). The wheel tractor scraper pictured is a single tractor scraper. Scrapers are also available as a **tandem scraper**. Tandem scrapers have separate engines for the tractor section wheels and the scraper section wheels. Having separate engines provides greater power and traction in rough terrain.

Like most types of MORE, motor graders range in size and capacity. However, most graders share some common features. They are long, narrow machines with a front-steering axle and two rear drive axles, both of which have rubber tires. A large diesel engine located at the rear of the grader provides the power to drive the grader and operate the hydraulic systems. All graders have an adjustable blade used to move soil or aggregate; cut ditches; and mix, windrow, grade, and smooth material. The blade is attached to the grader with a drawbar and a circle, which are controlled with hydraulic cylinders to maneuver the blade vertically, horizontally, and at an angle to the frame. Modern motor graders have articulated frames that allow them to work at an offset angle. **FIGURE 2-34** shows the major components of a motor grader.

FIGURE 2-33 Major components of a wheel tractor scraper.

FIGURE 2-34 Major components of a motor grader.

FIGURE 2-35 Major components of a vibratory steel-wheel roller.

Compactors are familiar-looking machines used to compact soil or pavement and speed up the natural settling process. Most compactors are self-propelled machines that have a diesel engine, an operator's cab with a steering wheel and other controls, and some combination of large metal rollers or pneumatic tires at the front and rear of the machine. A vibratory steel-wheel roller has a device on each drum that generates vibration to further enhance the compaction capabilities of the machine (**FIGURE 2-35**).

Hoisting and Handling Equipment Features

Equipment used for lifting, moving, and loading components and materials include machines such as cranes, forklifts, and knuckleboom loaders. Each of these types of equipment must be able to safely lift heavy objects high into the air and, in most cases, transport those objects to another area of the work site.

Cranes are among the most common machines used to lift and move heavy objects. A typical track-mounted (crawler) crane uses a boom, cables, and counterweights to

FIGURE 2-36 Major components of a track-mounted (crawler) crane.

FIGURE 2-37 Major components of a rough terrain forklift.

accomplish this task. Most crawler cranes have large diesel engines, hydraulic systems, joysticks for operator controls, and a high-strength lattice boom that can be raised and lowered (**FIGURE 2-36**).

Forklifts are used to move palletized components, sections of pipe, and similar materials from one place to another. The major features and controls of a typical rough terrain forklift are similar to those of any off-road forklift (**FIGURE 2-37**).

► MORE Terminology

K02003

Service technicians working on MORE must be familiar with basic terminology used to describe the features and operation of heavy equipment. Many of the components that make up heavy equipment are often called by different names. Failing to understand MORE terminology puts technicians at risk of misidentifying equipment parts and misunderstanding operating practices when they communicate with equipment owners and operators.

Construction Terminology

There are many industry terms used to describe the construction features of mobile off-road equipment. The following list identifies some of the more common terms with which technicians should be familiar.

Apron—a movable section on the forward wall of a scraper's bowl that is used to close the bowl for transport after the bowl is full.

Automatic retarder control system—an electronic system used on an off-road truck that works with the engine brake and traction control system to slow the vehicle during downhill travel.

Cutting edge—on a motor grader blade, a sharp steel bar attached to the bottom of the moldboard that is used for cutting into the ground.

Dipper stick (or stick)—the section of the digging component of an excavator that connects the end of the boom to the bucket.

Grouser—on a dozer, a ridge or cleat across a track that improves the track's grip.

Haul truck—a common name used to describe a rigid-frame dump truck or a mining truck.

Hoe—any kind excavator that digs material by having its bucket pulled from front to back. The term "hoe" is also used to describe the entire assembly at the front of an excavator that consists of the boom, stick, and bucket.

Hoist cylinders—the hydraulic cylinders on an off-road truck that are used to raise and lower the dump body.

Knuckleboom—a term that is sometimes used to describe the pivot point between a gooseneck boom and a stick that resembles a knuckle.

Moldboard—on a motor grader blade, the long concave piece of metal on which the cutting edge is attached to push soil or aggregate.

Outriggers—stabilizing devices that can be extended from the front and rear sides of a piece of equipment to keep it from tipping or rolling.

Pad (or foot)—on a sheepsfoot roller, the part of the roller that projects outward from the drum and makes contact with the ground.

Platen—a flat plate that serves as the supporting base for the rotating platform of an excavator.

Sheepsfoot—a tamping roller in which projected pads (or feet) extend outward from the drum to compact soil.

Shooting-boom excavator—another name for a telescoping boom excavator.

Traction control system—a computerized system used on off-road trucks to divert torque from a spinning wheel to one or more of the other wheels to improve traction.

Turntable—the rotating platform of an excavator.

Upper carriage—the upper frame of an excavator onto which the turntable, engine, operator's cab, operator controls, and counterweights are attached.

Upper structure—the part of a telescoping boom excavator that includes the turntable, swing mechanism, counterweight, boom, and operator's cab.

Operation Terminology

As with construction feature terms, there are numerous terms used to describe aspects of equipment operation. Service technicians should be familiar with these terms. The following list identifies common terms associated with the operation of MORE.

Blade float—allowing the blade of a dozer to float over a surface to create a smooth finish.

Blade pitch—the angle at which a dozer blade is from vertical.

Blade tilt—the angle at which a dozer blade is from horizontal.

Crowd—to move the stick of a backhoe closer to the tractor or to force the stick into digging.

Curl—to rotate the bucket of a backhoe.

Dozing—the process of using the blade on a dozer to push material to a different place.

Draw—to move the stick of a backhoe back toward the operator.

Grubbing—to use a bucket to dig out roots and other buried material.

Haul road—a compacted dirt road over which off-road trucks and equipment travel to move material on and off site.

Reach—to extend the stick of a backhoe away from the cab.

Ripping—using a ripper attachment on the back of a dozer or grader to loosen hard soil or other material.

Scarifying—using a scarifier attachment on a motor grader to loosen soil in front of the blade.

Spoils—excavated material that is removed during a digging operation.

Undercutting—the process of digging material from beneath an excavator or from a bank or vertical face of a trench.

► Industry/Accreditation

I02001

The construction and operation terminology presented in the previous section is critical for service technicians working on mobile off-road equipment. Technicians must be able to accurately use terminology that is common in the trade and understand safety procedures that apply to this work. Federal and state agencies and industrial trade groups have developed standards over the years that technicians can use for source material:

- The Occupational Safety and Health Administration (OSHA) at www.osha.gov, which sets and enforces standards related to safety and equipment.
- The Mine Safety and Health Administration (MSHA) at www.msha.gov, which develops and enforces safety and health rules pertaining to mines in the United States.
- The Association of Equipment Manufacturers (AEM) at www.aem.org, which develops industry best practices, offers training, and maintains safety and technical information.

In addition, magazines covering heavy equipment and off-road equipment manufacturers typically have technical information available on their websites. Technicians working on MORE should exploit all available resources to ensure that they understand the terminology and regulations that apply to the trade.

► MORE Attachments

K02004

Like a car or truck, nearly every type of MORE has optional equipment and special attachments that can greatly enhance the equipment's capability. For instance, excavators and backhoe loaders can be fitted with different sizes and types of buckets, and dozers can use different types of blades. This section examines some of the more common attachments used on MORE.

SAFETY TIP

Attachments used on MORE must be compatible with the specific equipment. Using an incompatible attachment can be extremely dangerous because the attachment could fail and seriously injure personnel or damage equipment.

Excavation Equipment Attachments

Excavators are often used for demolition work. One attachment that enables an excavator to fulfill this task is a hydraulic breaker. This hydraulic attachment is used primarily for breaking boulders, pavement, concrete, and other solid objects (**FIGURE 2-38**).

Other common attachments that are used on excavators include demolition shears, which can be used to cut through steel bars and beams; cutter heads, which can be used to grind up brush, stumps, and trees; rippers, which can be used to break up hard soil; and grapples, which can be used to grab and place material (**FIGURE 2-39**).

SAFETY TIP

Whenever a cutter head, a hydraulic breaker, or demolition shears are used as attachments on an excavator, a steel cage must be used in the front of the operator's cab to minimize the risk caused by flying debris.

Backhoe loader attachments are similar to those used on excavators. For instance, most backhoes can be fitted with different types of buckets to make them a versatile choice for excavation jobs that do not require the power of larger

FIGURE 2-38 Hydraulic breaker attachment and bits for an excavator.

FIGURE 2-39 MORE attachments: **A.** demolition shears **B.** cutter head **C.** ripper attachment **D.** grapple.

excavators. They can also be used with rippers and hydraulic breakers. Two other attachments that are often used on backhoe loaders are auger attachments, which can be used to bore holes for posts or piers, and cold planer attachments, which can be used to grind paved surfaces (**FIGURE 2-40**).

Earth-Moving and Mining Equipment Attachments

As with most heavy equipment that uses buckets or blades, a dozer can be fitted with any one of several blade options, depending on the specific need. In addition, dozers often use

FIGURE 2-40 Backhoe loader attachments: **A.** auger **B.** cold planer.

ripper attachments to break up hard soil, winches to pull material and other equipment, and side booms to lay pipe or cable (**FIGURE 2-41**).

Loaders can use some of the same types of attachments that are used on backhoe loaders and excavators. For instance, various sizes and types of buckets are available, as are grapples,

FIGURE 2-41 Dozer attachments: **A.** ripper **B.** winch **C.** side boom.

cold planers, and augers. Other attachments sometimes used on loaders include pallet forks, rotating brooms, and snow removal equipment.

Grading and Compacting Equipment Attachments

Two of the most common attachments used on motor graders are a scarifier and a ripper. Both of these attachments are used to break up hard soil, but a scarifier is located at the front of the grader ahead of the blade, whereas a ripper is located at the rear of the grader (**FIGURE 2-42**).

Hoisting and Handling Equipment Attachments

Equipment used for hoisting and handling material, including cranes, forklifts, and knuckleboom loaders, can be fitted with numerous attachments for special applications. For instance, cranes can use any of several types of hooks, grapples, and buckets to enhance their capabilities. They can also use pile driver attachments for driving posts or beams into the ground and wrecking balls to demolish buildings.

FIGURE 2-42 Motor grader attachments: **A.** scarifier **B.** ripper.

FIGURE 2-43 Forklift attachments.

Many of the attachments used on forklifts are designed to lift and carry specific shapes. For example, there are attachments for drums, rolls of paper, and blocks (**FIGURE 2-43**).

► MORE Systems and Components

K02005

The safe and effective operation of mobile off-road equipment depends on many factors. Some of the most important factors pertain to the systems and components found on the different types of equipment. These systems include those associated with steering, propulsion, the frame, and hydraulics.

Steering Systems

The overall design of a piece of heavy equipment and the particular type of steering system built into the equipment dictates whether the operator will use a steering wheel, levers, and pedals, or a joystick (tiller), to control the equipment. As a general rule, older pieces of track-mounted equipment used levers and pedals that operated mechanically. Modern track-mounted equipment uses hydraulic and electronic controls—typically joysticks (tillers), switches, and foot pedals (**FIGURE 2-44**).

Wheel-mounted equipment is more likely to use a steering wheel and foot pedals that resemble those used in a truck. A modern wheel loader, for instance, has a steering wheel and pedals to drive the vehicle, as well as a joystick and switches to control the function of the loader (**FIGURE 2-45**). The steering system itself is hydrostatic and uses two hydraulic cylinders to control the vehicle.

Propulsion Systems

Older pieces of heavy equipment used diesel engines, manual transmissions, and crawler tracks or wheels to operate and move. Many of these machines still exist today, and new machines are still being produced with manual

FIGURE 2-44 Operator controls in a modern hydraulic excavator cab.

FIGURE 2-45 Operator controls in a modern wheel loader cab.

transmissions—some of which have power reversers (power shuttles) and power shift options. Power reversers allow operators to change directions on a piece of equipment without having to use a foot clutch, stop the movement of the equipment, and manually shift into a forward or reverse gear. Power shift transmissions allow operators to change gears on the go without having to use a foot clutch.

Modern pieces of MORE use efficient diesel engines that range from 40 hp (30 kW) to about 600 hp (447 kW). These engines are often mated with heavy-duty (HD) hydrostatic transmissions that use pressurized fluid instead of gears to transfer power from the engine to the axles and wheels and provide infinitely variable speed. **FIGURE 2-46** shows a grader at work.

Equipment Frames

Different types of off-road equipment, such as dozers, graders, and trucks, are available with rigid frames or articulated frames (**FIGURE 2-47**). Choosing a frame for a piece of equipment depends on the strength, capacity, and mobility needed for the job. For instance, a rigid-frame haul truck in a mining application travels over established haul roads, so mobility is usually

FIGURE 2-46 A modern motor grader at work.

FIGURE 2-47 Rigid- and articulated-frame equipment: **A.** crawler dozer with rigid frame and **B.** wheel dozer with articulated frame.

not a mitigating factor. Brute strength, however, is a major concern. The capacity of a rigid-frame haul truck exceeds that of an articulated-frame truck. Articulated-frame trucks haul less, but they are very maneuverable and capable of traveling over muddy and rough terrain.

FIGURE 2-48 Wheel loader hydraulic system.

Hydraulic Systems

Hydraulic systems are one of the most important features on any kind of heavy equipment. A hydraulic system uses fluid power to greatly increase a machine's ability to lift, dig, grade, or perform other construction-related tasks. The system consists of many different components, including pumps, motors, valves, actuators, cylinders, and piping and hose (**FIGURE 2-48**).

By manipulating controls in the cab, an operator basically directs the flow of highly pressurized hydraulic fluid through the system to control the equipment.

SAFETY TIP

Working on or around hydraulic systems requires constant vigilance. The fluid in a hydraulic system is under great pressure and high temperature. Carelessly loosening a coupling or accidentally cutting a hose can release the fluid and subject personnel to serious injuries or burns.

► Attitude

A02001, S02001

Before starting, operating, or servicing any piece of MORE, it is important for technicians to be familiar with the equipment. This includes locating and reading any operator manuals and service manuals that may exist on site. Find out where those manuals are normally kept and take action to obtain the proper manuals for the equipment. If printed manuals are not available for the equipment, try to find electronic versions either from the client or online through the equipment manufacturer's website. It might also be possible to find the appropriate material by searching online. In some cases, it might be necessary to call the equipment manufacture to get the needed information. Whatever the means, it is important to ensure that the resource material being used matches the equipment being worked on. Follow the steps in **SKILL DRILL 2-1** to start, operate, and shut down a piece of MORE equipment.

SKILL DRILL 2-1 Starting, Operating, and Shutting Down Equipment

1. Obtain the necessary operator and service manuals that pertain to the equipment being serviced.

2. Perform a simple walk-around inspection of the equipment to ensure that there are no obvious problems, encroaching equipment, or personnel whose presence would prevent starting and moving the equipment.

3. Enter the cab or operator area of the equipment and use the operator's manual to familiarize yourself with the layout and controls used to operate the equipment.

4. Following the guidelines in the operator's manual, complete the necessary steps to start the equipment.

5. Once the equipment has reached its normal operating temperature, follow the steps in the operator's manual to move and operate the equipment. Always pay attention to the surroundings when moving and operating any piece of equipment.

6. After moving and operating the equipment, follow the steps in the operator's manual to safely stop, shut down, and secure the equipment.

Wrap-Up

Ready for Review

- ▶ MORE classifications can be based on different criteria, including which industry they serve, the general function of the equipment, the way equipment is propelled, or driven, and how the equipment is used.
- ▶ Many pieces of off-road equipment will often fit into several categories.
- ▶ An excavator is a piece of heavy equipment commonly used in earth-moving, trenching, and loading applications.
- ▶ Two basic types of excavators are standard hydraulic excavators: track-mounted machines with crawler tracks and wheel-mounted excavators, which use rubber tires.
- ▶ A typical backhoe loader has a hydraulically operated excavating arm mounted onto the rear of a rubber-tired tractor and a loader bucket attached to the front of the tractor.
- ▶ A trencher uses either a chain with cutting bits or a wheel with cutting teeth to dig trenches for burying pipes, cables, culverts, and similar items.
- ▶ A typical dozer, or bulldozer, is a heavy piece of equipment that moves on crawler tracks and has a wide blade mounted on the front to push large amounts of material.
- ▶ A loader has a large bucket mounted on the front that can be raised, lowered, and tilted so that it can scoop up material, transport it to a different area on the site, and dump it.
- ▶ A rigid-frame truck, which is sometimes called a haul truck or a mining truck, has a non-pivoting frame, a body, a front axle for steering, and a rear axle for transferring the engine's power to the wheels.
- ▶ An articulated-frame dump truck, or articulated hauler, has a pivoting point in the frame, is typically smaller than

rigid-frame truck, and is designed more for maneuverability in rough terrain than for sheer hauling capacity.

- ▶ An underground mining truck is much like an articulated-frame truck, but the operator's cab is moved forward of the front axle to give the truck a lower clearance.
- ▶ A scraper is a type of MORE that has a scraping edge that scrapes soil into a hopper so that it can be taken to another area to be dumped and dispersed.
- ▶ A motor grader is a long, narrow piece of MORE that has rubber tires, a large diesel engine, and an adjustable blade that is used in many earth-moving, ditching, grading, and smoothing applications.
- ▶ Motor graders can have rigid frames or articulated frames.
- ▶ Compactors are self-propelled machines equipped with large rollers or tires that are driven back and forth over soil, gravel, or asphalt to compact the material.
- ▶ Track-mounted (crawler) cranes have a high-strength lattice boom that can be raised, swung, and lowered to move heavy loads.
- ▶ Forklifts, or lift trucks, are used on construction sites to move palletized components, sections of pipe, and similar material from one place to another.
- ▶ A typical knuckleboom loader has a gooseneck boom with a hydraulically powered claw called a grapple that enables the loader to grab logs and other objects and move them onto piles or trucks.
- ▶ Machines found in any particular category of MORE share a lot of common features, even though they are manufactured by different companies around the world.
- ▶ A hydraulic breaker is an excavator attachment that is used primarily for breaking boulders, pavement, concrete, and other solid objects.
- ▶ A ripper is an attachment used on different pieces of MORE to break up hard soil.
- ▶ A scarifier is an attachment used on the front of a motor grader to break up soil ahead of the grader blade.

Key Terms

articulated frame A type of equipment frame that has a permanent hinge, or pivoting point, in the frame to enhance maneuverability.

canopy A part of the body of an off-road truck that extends above the cab to protect the operator from any falling material.

chain trencher A track-mounted trencher with a hydraulically controlled boom that uses a chain with cutting bits that travel around the boom to cut through hard soil and rock.

cumber bar A device on a chain trencher that follows the digging chain to prevent loose soil from collecting in the trench.

gooseneck boom A curved boom used on some types of equipment that connects to a dipper stick and bucket.

grapple A hydraulically powered claw that enables an operator to grab logs and other objects and move them onto piles or trucks.

lattice boom A type of boom commonly used on cranes that has a crisscross pattern of metal braces that enable it to lift heavy loads.

rigid frame A type of equipment frame that runs the full length of the equipment and has no pivoting points for articulation.

tandem scraper A type of scraper that has separate engines for the tractor section and the scraper section to provide greater power and traction for rough terrain.

telescoping boom A type of boom that can be extended outward and retracted.

undercarriage The lower frame of an excavator that supports the turntable and onto which the crawler tracks or wheels are attached.

wheel trencher A type of trencher that uses a large wheel with teeth to dig through pavement or hard soil.

Review Questions

1. The rotating platform on a standard hydraulic excavator can be rotated _____.
 - a. 90 degrees
 - b. 180 degrees
 - c. 270 degrees
 - d. 360 degrees
2. The primary purpose of a _____ is to push large amounts of soil, aggregate, or other material.
 - a. scraper
 - b. dozer
 - c. loader
 - d. telehandler
3. The height reduction of an underground mining truck is achieved by
 - a. replacing the crawler tracks with small diameter tires.
 - b. reducing the headroom inside the operator's cab.
 - c. moving the operator's cab forward of the front axle.
 - d. removing the cumber bar from the hopper.
4. Ditching, grading, and smoothing jobs are most likely to be accomplished using a(n) _____.
 - a. motor grader
 - b. tandem scraper
 - c. mobile crane
 - d. articulated loader
5. Wheel-mounted excavation equipment, such as excavators and backhoe loaders, use _____ for added stability.
 - a. lattices
 - b. outriggers
 - c. crumbers
 - d. canopies
6. A tandem scraper used in grading applications has two separate _____.
 - a. scarifiers
 - b. moldboards
 - c. hoppers
 - d. engines
7. The process of digging material from beneath an excavator or from a bank or vertical face of a trench is called _____.
 - a. scarifying
 - b. crowding
 - c. undercutting
 - d. grubbing

8. Which of the following excavator attachments can be used to cut through steel bars and beams during demolition work?
 - a. Demolition shears
 - b. Hydraulic breakers
 - c. Cutter heads
 - d. Grapple hooks
9. Side booms are best described as a type of
 - a. forklift attachment used to maximize horizontal load control.
 - b. haul truck attachment used to balance the body during unloading.
 - c. backhoe loader attachment used to widen the equipment's stance.
 - d. dozer attachment used to lay pipe or cable in trenches.
10. MORE engines are often mated with HD hydrostatic transmissions that use
 - a. motor oil to power hydraulic valves and provide infinitely variable pumping.
 - b. pressurized fluid to transfer power from the engine to the axles and wheels.
 - c. hardened gears and shafts that directly drive planetary gear sets in the wheels.
 - d. hydraulic cylinders located in the powertrain to move axles and wheels.

ASE Technician A/Technician B Style Questions

1. Technician A says the rotating platform on a standard hydraulic excavator is attached to an articulator beam that mounts to a chassis. Technician B says the rotating platform is attached to an undercarriage that has crawler tracks or wheels. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says the piece of equipment pictured here is a wheel-mounted excavator. Technician B says it is a skid steer loader. Who is correct?

- a. Technician A
- b. Technician B

- c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says a hydraulically controlled boom that can be lifted and lowered is used to control the depth of a trench being dug by a track-mounted chain trencher. Technician B says the depth is controlled by cutting bits that can be extended and retracted. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 4. Technician A says a loader is a piece of MORE that has a bucket designed to be raised, lowered, and tilted so that it can scoop up material, transport it to a different area on the site, and dump it. Technician B says a loader has a bucket designed to be raised, lowered, and tilted so that it can scoop up material and dump it into a truck. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 5. Technician A says that the part of an off-road truck's body that extends above the cab to protect the operator from falling material is called the gooseneck. Technician B says the part of the body that extends above the cab is the canopy. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 6. Technician A says a vibratory steel-wheel roller has a device on each drum that generates vibration to further enhance the compaction capabilities of the machine. Technician B says the device on each drum generates vibration to prevent seams from forming between different pavement layers. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 7. Technician A says a flat plate that serves as the supporting base for the rotating platform of an excavator is called an apron. Technician B says the flat plate being referred to is called a turntable. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 8. Technician A says one of the most common attachments used on a motor grader is a scarifier. Technician B says one of the most common motor grader attachments is a ripper. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

9. Technician A says attachments that are designed for moving objects such as drums, rolls of paper, and blocks are most likely to be used on a crane. Technician B says attachments for moving drums, rolls of paper, and blocks are most likely to be used on a forklift. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
10. Technician A says haul trucks used in mining applications typically have rigid frames because they travel over established haul roads with huge loads. Technician B says mining haul trucks typically have rigid frames because they require greater mobility than articulated-frame trucks. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

CHAPTER 3

Shop and Machine Safety

Knowledge Objectives

After reading this chapter, you will be able to:

- **K03001** Identify workplace hazards.
- **K03002** Describe industry practices for hazard assessment and control procedures.
- **K03003** Describe safety regulations, procedures, and occupational safety standards.
- **K03004** Describe the responsibilities of workers and employers to apply emergency procedures.
- **K03005** Describe the roles and responsibilities of employers and employees with respect to the selection and use of personal protective equipment (PPE).
- **K03006** Describe how to prepare a machine to safely service and repair it.

Skills Objectives

After reading this chapter, you will be able to:

- **S03001** Demonstrate the correct use of personal protection equipment.
- **S03002** Select, use, and maintain appropriate PPE for worksite applications.

Attitude Objectives

After reading this chapter, you will be able to:

- **A03001** Develop positive tradesperson attitudes with respect to housekeeping, personal protective equipment, and emergency procedures.
- **A03002** Apply appropriate safety procedures to workplace practices.

► Introduction

You probably know someone who has been, or have heard of a situation where someone has been, involved in a work-related accident or mishap. Work-related accidents and mishaps can result in severe personal injuries, damage to valuable equipment, and even death. This causes physical, emotional, and financial hardships for people and their families, lost revenue and production for repair shops, decreased morale of coworkers, and unnecessary inspections and oversight by government and industry authorities. The career you have chosen as a heavy equipment repair technician comes with many potential hazards and risks that can be reduced, but not eliminated. It is important to learn about hazards so that you can identify them and act to protect yourself and your coworkers. Some hazards are obvious, such as machines falling from hoists or jacks, or tires exploding during inflation. Other hazards are less obvious, such as the long-term effects of fumes from solvents. There are many things to learn about safety in the heavy equipment shop, but it is impossible to cover every situation you will encounter. If not properly handled, these hazards can result in accidents and mishaps that may cause equipment damage, severe injury to yourself and others, and even death. The key factor to lower the risk of an accident or mishap is safety. **Safety** is the condition of being protected from, or unlikely to cause danger, risk, or injury to yourself or others. This chapter will discuss some of the fundamental knowledge, attitudes, and actions to take in order to maintain a safe working environment.

The History of Safety in the Workplace

During the Industrial Revolution of the 1700s and 1800s, many people transitioned from working on farms and in the home to working in large industrial factories. This exposed many people to machinery and environments with safety risks they were not familiar with. During this time, very little attention was given by employers, and employees, to safety practices and risk mitigation techniques. As a result, many people were severely injured or killed, for what we would consider preventable causes today. Eventually, due to a large outcry from workers and their families, government and industry authorities began to implement rules and regulations governing safety in the workplace. Workplace safety has come a long way from its beginnings during the Industrial Revolution. You would likely be appalled by the

safety practices of an industrial factory during the 1700s or 1800s (**FIGURE 3-1**). History is very important to safety, because if we do not learn from past mistakes, we are likely to repeat them. Learning from your own past experiences and mistakes, as well as the experiences and mistakes of others, is crucial for the improvement of safety in the workplace over time.

Roles of Safety in the Workplace

To create and maintain a safe working environment, everyone must know their specific role, as well as the roles of others regarding safety. This extends all the way from employees, supervisors, managers, and company officers to vendors and government and industry authorities. **Occupational safety and health** is important to ensure that everyone can work without being injured. Governments will normally have legislation in place with significant penalties for those who do not follow safe practices in the workplace. Occupational safety and health is everyone's responsibility. You have a responsibility to ensure that you work safely and take care not to put others at risk by acting in an unsafe manner. Supervisors and managers have a responsibility not to expose employees under their responsibility to risks, without providing employees with knowledge of the risks and appropriate safety measures. Your employer also has a responsibility to provide a safe working environment.

FIGURE 3-1 Workplaces until the last hundred years or so were unsafe and dirty environments. Injuries and deaths in the workplace were commonplace.

You Are the Mobile Heavy Equipment Technician

You are assisting another technician with repairs to a tractor loader backhoe. One of the mechanical linkages on the rear shovel of the backhoe has cracked and needs to be welded. The other technician wants to use an electric arc welder to perform the repair with the linkage left in place, as removing it would be difficult and time-consuming. The area where you will be performing the repair is very busy, with many people working.

1. What types of hazards are present during a welding operation with an electric arc welder?
2. What types of personal protective equipment (PPE) should you both use to protect yourself from welding hazards?
3. What measures (if any) should be taken to protect other people in the area from welding hazards?
4. What (if any) preparations should be made to protect yourself, other people, and equipment before welding begins?

Government regulators have a responsibility to enforce the law. Because safety is everyone's responsibility, anyone has the authority to stop an operation that is unsafe, in order to make corrections.

The Role of Hazard Prevention and Control in Safety in the Workplace

Not all **hazards** and **risks** in the workplace can be prevented or eliminated. The key is to apply the appropriate **risk controls**, to minimize the risk to personnel and equipment from workplace hazards. When appropriate risk controls are in place to protect employees and equipment from workplace hazards, they benefit everyone involved. The benefits of an effective workplace hazard prevention and control system include:

- avoiding unnecessary injuries and illnesses to personnel
- minimizing or eliminate unnecessary safety and health risks
- minimizing decreased production due to lost time safety incidents
- minimizing downtime due to equipment damage from safety mishaps
- increasing employee health
- increasing employee morale and job satisfaction.

To create and maintain a safe working environment, both employees and management must be committed to safety. The largest factor that can affect safety in a positive or negative way is *you*. This requires you to have the correct knowledge so that you know what to do and for you to act on that knowledge by performing the action correctly. Most accidents occur because of human factors. This means an individual did not know the correct action to perform, or they did know the correct action but did not perform the action correctly. To ensure the safety of yourself and others, make sure you are aware of the correct safety procedures at your workplace. This means listening carefully to safety information provided by your employer and asking for clarification, help, or instructions if you are unsure how to perform a task safely. Always think about how you are performing shop tasks, be on the lookout for unsafe equipment and work practices, and wear the correct **personal protective equipment (PPE)**. PPE refers to safety equipment like safety footwear, gloves, clothing, protective eyewear, and hearing protection (**FIGURE 3-2**).

Know the location of emergency equipment like fire extinguishers, defibrillators, and first aid kits, as well as the designated **evacuation routes**. Evacuation routes are a safe way of escaping danger and gathering in a safe place where everyone can be accounted for in the event of an emergency. It is important to have more than one evacuation route in case any single route is blocked during the emergency. Your shop may have an evacuation procedure that clearly identifies the evacuation routes (**FIGURE 3-3**). The evacuation routes will often be marked with colored lines painted on the floors. Exits should be highlighted with signs that may be illuminated. Always make sure

FIGURE 3-2 PPE refers to safety equipment like gloves, safety-toe work boots, eye protection, and hearing protection.

FIGURE 3-3 Your shop should have an evacuation route plan posted in several places throughout your shop.

you are familiar with the evacuation routes for the shop. Before conducting any task, identify which route you will take if an emergency were to occur. Muster points are usually identified outside of the shop and provide a safe gathering area where a designated individual can perform a roll call to ensure that everyone is accounted for.

► TECHNICIAN TIP

Emergency Evacuation Routes and Exits: Keep emergency evacuation routes and exits clear of tools, equipment, parts, or machines. Never block, lock, or obstruct emergency exits. Doing so may prevent prompt evacuation in case of an emergency.

Remember that safety is everyone's responsibility! In this chapter, we will introduce the fundamental concepts of safety in the workplace, so that you will have the knowledge to work safely. It is up to you to take the correct actions to keep yourself and others safe in your workplace.

► Identification of Workplace Hazards

K03001

A **hazard** is anything that could hurt you or someone else, and most workplaces have them. It is almost impossible to remove all hazards in the workplace, but it is important to recognize and identify hazards and work to reduce their potential for causing harm by putting specific **hazard control measures** in place. Hazard control measures are processes and procedures put into place to reduce or eliminate the risk and/or severity of an accident or mishap. For example, operating a bench grinder poses several hazards. While it is not possible to eliminate the hazards of using the bench grinder, by putting specific hazard control measures in place, the risk of those hazards can be reduced. A risk analysis of a bench grinder would identify the following hazards and risks: a high-velocity particle that could damage your eyesight or that of someone working nearby; the grinding wheel breaking apart, damaging eyesight or causing cuts and abrasion; electrocution if electrical parts are faulty; heat or high-velocity particles damaging your hands; a risk to your hearing due to excessive noise; and a risk of entrapment of clothing or body parts through rotating machinery. To reduce the risk of these hazards, the following measures are taken: position the bench grinder in a safe area away from where others work; make sure electrical items are regularly checked for electrical and mechanical safety, when operating the equipment wear PPE such as protective eyewear, gloves, hearing protection, hairnets, or caps; do not wear loose clothing that can be caught in the bench grinder; and ensure that all guards and safety devices specified by the manufacturer are in place. Unidentified hazards have the greatest potential to cause a workplace accident or mishap. Therefore, it is important to have processes in place that constantly seek to identify new hazards in the workplace. At many shops, hazards may already be identified for you during training and new employee orientation. Hazards may also be identified for you through signage on specific machines or in certain areas where hazards exist. You may be educated on specific workplace hazards by shop safety managers or in periodic safety updates and memos. While many shops are very proactive in identifying hazards for their employees, this does not relieve each person of their responsibility for their own safety. Just as the hazards most likely to cause an accident or mishap are the unidentified hazards, so too the people most likely to be involved in an accident or mishap are those who do not familiarize themselves with their work environment and hazard related information.

Hazardous Environments

A **hazardous environment** is a place where hazards exist. Most workplaces have some type of hazards, but the type or hazard and severity of the risk can vary. For example, the risk to an employee in a coffee shop is quite different from the risk to an employee in a heavy equipment shop that repairs mobile off-road equipment. It is much less likely that an employee at a coffee shop may be killed due to not familiarizing themselves

with the hazards in their working environment. In contrast, an employee at a heavy equipment shop with potentially dangerous equipment around, such as overhead cranes, equipment lifts and jacks, welding equipment, and power tools, has a much greater potential to be severely injured or killed by not familiarizing themselves with the hazards in the work environment. Your employer could identify every hazard with clear signage and invest heavily in an effective safety program, but if you do not familiarize yourself with the hazards of your work environment, you are a potential danger to yourself and others. An important first step in identifying hazardous environments is to familiarize yourself with the shop layout. If it is not already part of your employer's new-hire or onboarding process, ask your supervisor or another employee to provide a tour of the shop to you. Ask about, and pay attention to, the locations and types of hazards and their respective control measures: fire extinguishers, fire alarms, exhaust ventilation hoses, hazardous and flammable material storage, spill kits, and the location of material safety data sheets and other safety-related documentation. There may be special work areas that are defined by painted lines. These lines show the hazardous zone around certain machines and areas. If you are not working on the machines, you should stay outside the marked area. Study the various warning signs around your shop. Understand the meaning of the signal word, the colors, the text, and the symbols or pictures on each sign. Ask your supervisor if you do not fully understand any part of a sign. To identify hazardous environments, follow the steps in

SKILL DRILL 3-1.

Hazard Signs

Always remember that a shop is a hazardous environment. To make people more aware of specific shop hazards, legislative bodies have developed a series of safety signs. These signs are designed to give adequate warning of an unsafe situation. Each sign has four components:

- **Signal word:** There are three signal words—danger, warning, and caution.
 - Danger** indicates an immediately hazardous situation, which, if not avoided, will result in death or serious injury. Danger is usually indicated by white text with a red background. See **FIGURE 3-4A** for an example of warning signage.
 - Warning** indicates a potentially hazardous situation, which, if not avoided, could result in death or serious injury. The sign is usually in black text with a yellow or orange background. See **FIGURE 3-4B** for an example of warning signage.
 - Caution** indicates a potentially hazardous situation, which, if not avoided, may result in minor or moderate injury. It may also be used to alert people about unsafe practices. This sign is usually in black text with a yellow background. See **FIGURE 3-4C** for an example of a caution sign.
- **Background color:** The choice of background color also draws attention to potential hazards and is used to provide contrast so that the letters or images stand out. For example, a red background is used to identify a definite hazard; yellow indicates caution for a potential hazard. A green background is used for emergency-type signs, such

SKILL DRILL 3-1 Identifying Hazardous Environments

1. Familiarize yourself with the shop layout. Study and understand the various warning signs around your shop. Identify exits and plan your escape route in case of emergency. Know the designated gathering point, and go there in an emergency.

2. Check the air quality. Locate the extractor fans or ventilation outlets, and make sure they are not obstructed in any way. Locate and observe the operation of the exhaust extraction hose, pump, and outlet used on a machine's exhaust pipes.

3. Check the location, type, and operation of fire extinguishers and fire alarms in your shop. Be sure you know when and how to use each type of fire extinguisher.

4. Find out where flammable materials are kept, and make sure they are stored properly.

5. Check the hoses and fittings on the air compressor and air guns for any damage or excessive wear. Be particularly careful when troubleshooting air guns. Never pull the trigger while inspecting one: severe eye damage can result.

6. Identify caustic chemicals and acids associated with activities in your shop. Ask your supervisor for information on any special hazards in your particular shop and any special avoidance procedures that may apply to you and your working environment.

7. Identify the location and proper operation of the emergency eye wash station in your shop.

8. Identify the location, and verify the contents of the spill kits located in your shop.

9. Identify the location of material safety data sheets and other safety-related documentation in your shop.

FIGURE 3-4 Standard Hazard Signage **A.** Danger is usually indicated by white text on a red background. **B.** Warning is usually in black text with an orange background. **C.** Caution is usually in black text with a yellow background.

as for first aid, fire protection, and emergency equipment. A blue background is used for general information signs.

- **Text:** The sign will sometimes include explanatory text intended to provide additional safety information. Some signs are designed to convey a personal safety message.

- **Pictorial message:** In symbol signs, a pictorial message appears alone or is combined with explanatory text. This type of sign allows the safety message to be conveyed to people who are illiterate or who do not speak the local language.

Safety Equipment

Shop safety equipment includes the following items:

- **Handrails:** Handrails are used to separate walkways and pedestrian traffic from work areas. They provide a physical barrier that directs pedestrian traffic and also provide protection from machine movements.
- **Machinery guards:** Machinery guards and yellow lines prevent people from accidentally walking into the operating equipment, or they indicate that a safe distance should be kept from the equipment.
- **Painted lines:** Large, fixed machinery such as lathes and milling machines present a hazard to the operator and others working in the area. To prevent accidents, a machinery guard or a yellow painted line on the floor usually borders this equipment.
- **Soundproof rooms:** Soundproof rooms are usually used when a lot of noise is made by operating equipment. An example is the use of a chassis dynamometer. A vehicle operating on a dynamometer produces a lot of noise from its tires, exhaust, and engine. To protect other shop users from the noise, the dynamometer is usually placed in a soundproof room to keep shop noise to a minimum.
- **Adequate ventilation:** Exhaust gases in shops are a serious health hazard. Whenever a machine's engine is running, toxic gases are emitted from its exhaust. To prevent an excess of toxic gas buildup, a well-ventilated work area is needed as well as a method of directly venting the machine's exhaust to the outside.
- **Gas extraction hoses:** The best way to get rid of these gases is with a suction hose that fits over the machine's exhaust pipe. The hose is attached to an extraction pump that vents the gas to the outside.
- **Doors and gates:** Doors and gates are used for the same reason as machinery guards and painted lines. A doorway is a physical barrier that can be locked and sealed to separate a hazardous environment from the rest of the shop or a general work area from an office or specialist work area.
- **Temporary barriers:** In the day-to-day operation of a shop, there is often a reason to temporarily separate one work bay from others. If a welding machine or an oxyacetylene cutting torch is in use, it may be necessary to place a temporary screen or barrier around the work area to protect other shop users from welding flash or injury.

► TECHNICIAN TIP

Stay alert for hazards or anything that might be dangerous. If you see, hear, or smell anything odd, take steps to fix it or tell your supervisor about the problem.

► TECHNICIAN TIP

Whenever you perform a task in the shop, you must use personal protective clothing and equipment that are appropriate for the task and that conform to your local safety regulations and policies. Among other items, these may include the following:

- work clothing, such as coveralls and safety toed footwear
- eye protection, such as safety glasses and face masks
- ear protection, such as earmuffs and earplugs
- hand protection, such as gloves and barrier cream
- respiratory equipment, such as face masks and respirators.

If you are not certain what is appropriate or required, ask your supervisor.

Technical Manuals in Hazard Identification

Reading and familiarizing yourself with the **technical manual** for the equipment you are operating or servicing is vital to hazard identification. Equipment manufacturers may publish separate operating and servicing manuals, or they may be combined into a single text. Manufacturers include the most complete information on specific hazards and safety-related information in their technical manuals. Before operating or servicing any equipment, especially for the very first time, you should read and become familiar with the manufacturer's technical manual, paying attention to the hazards and safety-related information. The manufacturer's technical manuals can be considered the most complete and correct information on the equipment, which include hazards and safety information. Not all hazards are marked with signage on the equipment itself, which is why it is important to read the technical manual and note any hazard and safety information. Periodically, manufacturers may issue updates or supplements to their technical manuals, which may include hazard and safety-related information. Because of this, it is important to include any updates to technical manuals and publications as soon as they are released by the manufacturer. If a hard copy manual isn't available, one can often be obtained online and downloaded. Ensure that the manual that is downloaded is the exact one for the machine or equipment that you are working on. The information contained in the manufacturer technical manuals is one of your best tools to avoid workplace accidents and mishaps (FIGURE 3-5).

Specific Machine and Shop Safety Hazards

When employed at a workplace that services automotive or mobile off-road equipment, there are some common hazards that may be present. In the next paragraphs, we will briefly discuss some of these common hazards.

Hazardous Materials

A **hazardous material** is any material that poses an unreasonable risk of damage or injury to persons, property, or the environment if it is not properly controlled during handling, storage, manufacture, processing, packaging, use and disposal, or transportation. These materials can be solids, liquids, or

FIGURE 3-5 An equipment manufacturer's operating and repair manuals are a critical source for safety-related information and warnings.

FIGURE 3-6 Hazardous materials can be liquids, solids, or gases. All hazardous materials are dangerous.

gases (FIGURE 3-6). Most shops use hazardous materials daily, such as cleaning solvents, spray paint, gasket cement, brake fluid, and coolant. Hazardous materials must be properly handled, labeled, stored, and cleaned in the event of a spill.

Hazardous Material Spill Kits

A **spill kit** is a kit used in workplaces that use or store liquid hazardous material and other liquids that require special cleanup procedures (FIGURE 3-7). These kits contain items needed in the cleanup of a liquid hazardous material spill. A spill kit may contain gloves, eye protection, rubber apron, absorbent pads, barrier materials, sand or other absorbent loose material. Ensure you know the location of spill kits in your shop. Spill kits should be inspected regularly and restocked as needed. Before using a spill kit to cleanup any liquid or hazardous material spill, read the **material safety data sheet (MSDS)** for the material and follow the cleanup and disposal instructions. If in doubt about proper cleanup and disposal procedures, contact the material manufacturer at the telephone number on the MSDS or the product label.

FIGURE 3-7 Spill kits should be located in areas where spills are most likely to occur.

► TECHNICIAN TIP

Hazardous material spill kits: The technician should know where the spill kits are in their work area. In the event of a spill, first clear the area. Next, read the **Safety data sheet (SDS)** for the spilled material to determine what to do in case of a spill and the proper way to clean up and dispose of the spilled material. If further details are needed, contact the material manufacturer at the telephone number listed on the SDS.

Material Safety Data Sheets

Hazardous materials are used daily and may make you very sick if they are not used properly. The manufacturers of all hazardous materials are required to provide an SDS also called an MSDS, which provides specific information on the hazards associated with the material. MSDS contain detailed information about the hazardous materials to help you understand how they should be safely used, any health effects relating to them, how to treat a person who has been exposed to them, and how to deal with them in a fire situation. An MSDS can be obtained from the manufacturer of the material. The shop should have an MSDS for each hazardous substance or dangerous product they have. In the United States, it is required that workplaces have an MSDS for every chemical on site. Whenever you deal with a potentially hazardous product, you should consult the MSDS to learn how to use that product safely. If you are using more than one product, make sure you consult all the MSDS for those products. Be aware that certain combinations of products can be more dangerous than any of them separately. MSDS are usually kept in a clearly marked binder and should be regularly updated as chemicals come into the workplace. See **FIGURE 3-8** for an example of an MSDS. Generally, the SDS must contain at least the following information:

- revision date
- material and manufacturer ID
- hazardous ingredients
- health hazard data
- fire and explosion data
- details about the material mixing or reacting with other materials
- special precautions.

Review the following figures for an example of an SDS. To identify information found on an SDS, follow the steps in **SKILL DRILL 3-2**.

Engine Exhaust Hazards

Running engines produce dangerous exhaust gases, including carbon monoxide and carbon dioxide. Carbon monoxide in even small concentrations can kill or cause serious injuries. Carbon dioxide is a greenhouse gas, and vehicles are a major source of carbon dioxide in the atmosphere. Exhaust gases also contain hydrocarbons and nitrogen oxides. These gases can form smog and cause breathing problems for some people.

Carbon monoxide is extremely dangerous, as it is odorless and colorless and can build up to toxic levels very quickly in confined spaces. In fact, it doesn't take very much carbon monoxide to pose a danger. The maximum permissible exposure limit (PEL) for **OSHA (Occupational Safety and Health Administration)** is 50 parts per million (ppm) of air for an eight-hour period. The National Institute for Occupational Safety and Health has established a recommended exposure limit of 35 ppm for an eight-hour period. The PEL is so low is because carbon monoxide attaches itself to red blood cells much more easily than oxygen does, and it stays with the blood cell. This prevents the blood cells from carrying as much oxygen, and if enough carbon monoxide has been inhaled, it effectively asphyxiates the person. Always follow the correct safety precautions when running engines indoors or in a confined space, including over service pits since gases can accumulate there. The best solution when running engines in an enclosed space is to directly couple the machine's exhaust pipe to an exhaust extraction system that will ventilate the fumes away from the enclosed space to the outside air (**FIGURE 3-9**). The extraction system should be vented to where the fumes will not be drawn back indoors, to a place well away from other people and other premises.

Do not assume that a gasoline engine fitted with a catalytic converter can be run safely indoors; it cannot. Catalytic converters are fitted into the exhaust system in a similar way as mufflers and have a ceramic core with a catalyst that when in operation, controls exhaust emissions through chemical reaction. Diesel trucks and machines equipped with after-treatment exhaust systems operate in much the same manner, and the same safety precautions should be taken with a running diesel truck or machine. They require high temperatures to operate efficiently and are less effective when the exhaust gases are relatively cool, such as when the engine is only idling or being run intermittently. A catalytic converter can never substitute for adequate ventilation or exhaust extraction equipment. In fact, even if the catalytic converter were working at 100% efficiency, the exhaust would contain large amounts of carbon dioxide and very low amounts of oxygen; neither condition can sustain human life.

SAFETY TIP

Do not operate gasoline/petrol or diesel engine equipment indoors without proper exhaust extraction hoses attached for ventilation.

SAFETY DATA SHEET

1. Identification

Product identifier	Brakleen® Brake Parts Cleaner
Other means of identification	
Product code	05089, 05089T, 85089, 85089AZ
Recommended use	Brake cleaner
Recommended restrictions	None known.
Manufacturer/Importer/Supplier/Distributor information	
Manufactured or sold by:	
Company name	CRC Industries, Inc.
Address	885 Louis Dr. Warminster, PA 18974 US
Telephone	
General Information	215-674-4300
Technical Assistance	800-521-3168
Customer Service	800-272-4620
24-Hour Emergency (CHEMTREC)	800-424-9300 (US) 703-527-3887 (International)
Website	www.crcindustries.com

2. Hazard(s) identification

Physical hazards	Gases under pressure	Compressed gas
Health hazards	Skin corrosion/irritation	Category 2
	Carcinogenicity	Category 1B
	Specific target organ toxicity, single exposure	Category 3 narcotic effects
Environmental hazards	Hazardous to the aquatic environment, long-term hazard	Category 2
OSHA defined hazards	Not classified.	
Label elements		

Signal word Danger

Hazard statement Contains gas under pressure; may explode if heated. Causes skin irritation. May cause drowsiness or dizziness. May cause cancer. Toxic to aquatic life with long lasting effects.

Precautionary statement
Prevention

Obtain special instructions before use. Do not handle until all safety precautions have been read and understood. Do not puncture or incinerate container. Do not expose to heat or store at temperatures above 49°C/120°F. Use with adequate ventilation. Open doors and windows or use other means to ensure a fresh air supply during use and while product is drying. If you experience any symptoms listed on this label, increase ventilation or leave the area. Avoid breathing mist or vapor. Avoid breathing gas. Wash thoroughly after handling. Wear protective gloves/protective clothing/eye protection/face protection. Avoid release to the environment.

Response

If on skin: Wash with plenty of water. If skin irritation occurs: Get medical attention. Take off contaminated clothing and wash before reuse. If inhaled: Remove person to fresh air and keep comfortable for breathing. Call a poison center/doctor if you feel unwell. If exposed or concerned: Get medical attention. Collect spillage.

Storage

Store locked up. Protect from sunlight. Store in a well-ventilated place. Exposure to high temperature may cause can to burst.

Disposal

Dispose of contents/container in accordance with local/regional/national regulations.

3. Composition/information on ingredients

Mixtures

Chemical name	Common name and synonyms	CAS number	%
Tetrachloroethylene	Perchloroethylene	127-18-4	90 - 100
Carbon dioxide		124-38-9	1 - 5

Specific chemical identity and/or percentage of composition has been withheld as a trade secret.

Material name: Brakleen® Brake Parts Cleaner

SDS US

1 / 9

FIGURE 3-8 An example of an SDS with key areas highlighted.

4. First-aid measures

Inhalation	Remove victim to fresh air and keep at rest in a position comfortable for breathing. Call a POISON CENTER or doctor/physician if you feel unwell.
Skin contact	Remove contaminated clothing. Rinse skin with water/shower. If skin irritation occurs: Get medical advice/attention. Wash contaminated clothing before reuse.
Eye contact	Rinse with water. Get medical attention if irritation develops and persists.
Ingestion	In the unlikely event of swallowing contact a physician or poison control center. Rinse mouth.
Most important symptoms/effects, acute and delayed	May cause drowsiness and dizziness. Headache. Nausea, vomiting. Irritation of eyes and mucous membranes. Irritation of nose and throat. Skin irritation. May cause redness and pain.
Indication of immediate medical attention and special treatment needed	Provide general supportive measures and treat symptomatically. Keep victim under observation. Symptoms may be delayed.
General information	IF exposed or concerned: Get medical advice/attention. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves.

5. Fire-fighting measures

Suitable extinguishing media	Dry chemical, CO ₂ , or water spray.
Unsuitable extinguishing media	Do not use water jet as an extinguisher, as this will spread the fire.
Specific hazards arising from the chemical	Contents under pressure. Exposure to high temperature may cause can to burst. When exposed to extreme heat or hot surfaces, vapors may decompose to harmful or fatal corrosive gases such as hydrogen chloride and possibly phosgene.
Special protective equipment and precautions for firefighters	Firefighters must use standard protective equipment including flame retardant coat, helmet with face shield, gloves, rubber boots, and in enclosed spaces, SCBA.
Fire-fighting equipment/instructions	In case of fire: Stop leak if safe to do so. Move containers from fire area if you can do so without risk. Containers should be cooled with water to prevent vapor pressure build up.

6. Accidental release measures

Personal precautions, protective equipment and emergency procedures	Keep unnecessary personnel away. Keep people away from and upwind of spill/leak. Keep out of low areas. Wear appropriate protective equipment and clothing during clean-up. Avoid breathing mist or vapor. Avoid breathing gas. Do not touch damaged containers or spilled material unless wearing appropriate protective clothing. Ensure adequate ventilation. Local authorities should be advised if significant spillages cannot be contained. For personal protection, see section 8 of the SDS.
Methods and materials for containment and cleaning up	Eliminate all ignition sources (no smoking, flares, sparks, or flames in immediate area). Keep combustibles (wood, paper, oil, etc.) away from spilled material. This material is classified as a water pollutant under the Clean Water Act and should be prevented from contaminating soil or from entering sewage and drainage systems which lead to waterways. Stop the flow of material, if this is without risk. Collect spillage. Wipe up with absorbent material (e.g. cloth, fleece). Clean surface thoroughly to remove residual contamination. For waste disposal, see section 13 of the SDS.
Environmental precautions	Avoid release to the environment. Contact local authorities in case of spillage to drain/aquatic environment. Prevent further leakage or spillage if safe to do so. Do not contaminate water. Avoid discharge into drains, water courses or onto the ground.

7. Handling and storage

Precautions for safe handling	Obtain special instructions before use. Do not handle until all safety precautions have been read and understood. Pressurized container: Do not pierce or burn, even after use. Do not use if spray button is missing or defective. Do not spray on a naked flame or any other incandescent material. Do not smoke while using or until sprayed surface is thoroughly dry. Use with adequate ventilation. Open doors and windows or use other means to ensure a fresh air supply during use and while product is drying. If you experience any symptoms listed on this label, increase ventilation or leave the area. Do not cut, weld, solder, drill, grind, or expose containers to heat, flame, sparks, or other sources of ignition. Use caution around energized equipment. The metal container will conduct electricity if it contacts a live source. This may result in injury to the user from electrical shock and/or flash fire. Avoid breathing mist or vapor. Avoid breathing gas. Avoid contact with eyes, skin, and clothing. Avoid prolonged exposure. Use only in well-ventilated areas. Should be handled in closed systems, if possible. Wear appropriate personal protective equipment. Observe good industrial hygiene practices. Avoid release to the environment. Do not empty into drains. For product usage instructions, please see the product label.
Conditions for safe storage, including any incompatibilities	Level 1 Aerosol. Contents under pressure. Do not puncture or incinerate container. Do not expose to heat or store at temperatures above 49 °C/120 °F. Do not handle or store near an open flame, heat or other sources of ignition. Exposure to high temperature may cause can to burst. Store in a well-ventilated place. Store away from incompatible materials (see Section 10 of the SDS).

8. Exposure controls/personal protection

Occupational exposure limits

US. OSHA Table Z-1 Limits for Air Contaminants (29 CFR 1910.1000)

Components	Type	Value
Carbon dioxide (CAS 124-38-9)	PEL	9000 mg/m ³

FIGURE 3-8 (Continued)

10. Stability and reactivity

Reactivity	The product is stable and non-reactive under normal conditions of use, storage and transport.
Chemical stability	Material is stable under normal conditions.
Possibility of hazardous reactions	No dangerous reaction known under conditions of normal use.
Conditions to avoid	Heat, flames and sparks. Contact with incompatible materials. When exposed to extreme heat or hot surfaces, vapors may decompose to harmful or fatal corrosive gases such as hydrogen chloride and possibly phosgene.
Incompatible materials	Strong oxidizing agents. Strong acids. Strong bases.
Hazardous decomposition products	Hydrogen chloride. Trace amounts of chlorine and phosgene. Carbon oxides. Halogenated materials. Carbonyl halides.

11. Toxicological information

Information on likely routes of exposure

Inhalation	Prolonged inhalation may be harmful. May cause drowsiness and dizziness. Headache. Nausea, vomiting.
Skin contact	Causes skin irritation.
Eye contact	Direct contact with eyes may cause temporary irritation.
Ingestion	Ingestion of large amounts may produce gastrointestinal disturbances including irritation, nausea, and diarrhea.

Symptoms related to the physical, chemical and toxicological characteristics
May cause drowsiness and dizziness. Headache. Nausea, vomiting. Irritation of nose and throat. Irritation of eyes and mucous membranes. Skin irritation. May cause redness and pain.

Information on toxicological effects

Acute toxicity Narcotic effects.

Product	Species	Test Results
Brakleen® Brake Parts Cleaner		
Acute		
<i>Dermal</i>		
LD50	Rabbit	3305.1284 mg/kg estimated
<i>Inhalation</i>		
LC50	Rat	20.4779 mg/l, 4 Hours estimated
<i>Oral</i>		
LD50	Rat	2691.8162 mg/kg estimated

* Estimates for product may be based on additional component data not shown.

Skin corrosion/irritation	Causes skin irritation.
Serious eye damage/eye irritation	Direct contact with eyes may cause temporary irritation.
Respiratory sensitization	Not available.
Skin sensitization	This product is not expected to cause skin sensitization.
Germ cell mutagenicity	No data available to indicate product or any components present at greater than 0.1% are mutagenic or genotoxic.
Carcinogenicity	May cause cancer.

IARC Monographs. Overall Evaluation of Carcinogenicity

Tetrachloroethylene (CAS 127-18-4) 2A Probably carcinogenic to humans.

US. National Toxicology Program (NTP) Report on Carcinogens

Tetrachloroethylene (CAS 127-18-4) Reasonably Anticipated to be a Human Carcinogen.

Reproductive toxicity	This product is not expected to cause reproductive or developmental effects.
Specific target organ toxicity - single exposure	May cause drowsiness and dizziness.
Specific target organ toxicity - repeated exposure	Not classified.
Aspiration hazard	May be an aspiration hazard.
Chronic effects	Prolonged inhalation may be harmful. Prolonged exposure may cause chronic effects.

12. Ecological information

Ecotoxicity Toxic to aquatic life with long lasting effects. Accumulation in aquatic organisms is expected.

Product	Species	Test Results
Brakleen® Brake Parts Cleaner		
Aquatic		
Fish	LC50	19.1805 mg/l, 96 hours estimated
Components	Species	Test Results
Tetrachloroethylene (CAS 127-18-4)

13. Disposal considerations

Disposal of waste from residues / unused products	This material and its container must be disposed of as hazardous waste. Consult authorities before disposal. Contents under pressure. Do not puncture, incinerate or crush. Do not allow this material to drain into sewers/water supplies. Do not contaminate ponds, waterways or ditches with chemical or used container. Dispose in accordance with all applicable regulations.
Hazardous waste code	D039: Waste Tetrachloroethylene F001: Waste Halogenated Solvent - Spent Halogenated Solvent Used in Degreasing F002: Waste Halogenated Solvent - Spent Halogenated Solvent
US RCRA Hazardous Waste U List: Reference	
Tetrachloroethylene (CAS 127-18-4)	U210
Contaminated packaging	Empty containers should be taken to an approved waste handling site for recycling or disposal. Since emptied containers may retain product residue, follow label warnings even after container is emptied.

14. Transport information

DOT	
UN number	UN1950
UN proper shipping name	Aerosols, poison, Packing Group III, Limited Quantity, MARINE POLLUTANT
Transport hazard class(es)	
Class	2.2
Subsidiary risk	6.1(PGIII)
Label(s)	2.2, 6.1
Packing group	Not applicable.
Environmental hazards	
Marine pollutant	Yes
Special precautions for user	Read safety instructions, SDS and emergency procedures before handling.
Special provisions	Not available.
Packaging exceptions	306
Packaging non bulk	None
Packaging bulk	None
IATA	
UN number	UN1950
UN proper shipping name	Aerosols, non-flammable, containing substances in Division 6.1, Packing Group III, Limited Quantity

15. Regulatory information

US federal regulations	This product is a "Hazardous Chemical" as defined by the OSHA Hazard Communication Standard, 29 CFR 1910.1200.
TSCA Section 12(b) Export Notification (40 CFR 707, Subpt. D)	Not regulated.
SARA 304 Emergency release notification	Not regulated.
US. OSHA Specifically Regulated Substances (29 CFR 1910.1001-1050)	Not listed.
US EPCRA (SARA Title III) Section 313 - Toxic Chemical: Listed substance	Tetrachloroethylene (CAS 127-18-4)
CERCLA Hazardous Substance List (40 CFR 302.4)	Tetrachloroethylene (CAS 127-18-4)
CERCLA Hazardous Substances: Reportable quantity	Tetrachloroethylene (CAS 127-18-4) 100 LBS
	Spills or releases resulting in the loss of any ingredient at or above its RQ require immediate notification to the National Response Center (800-424-8802) and to your Local Emergency Planning Committee.
Clean Air Act (CAA) Section 112 Hazardous Air Pollutants (HAPs) List	Tetrachloroethylene (CAS 127-18-4)
Clean Air Act (CAA) Section 112(r) Accidental Release Prevention (40 CFR 68.130)	Not regulated.
Safe Drinking Water Act (SDWA)	Not regulated.
Food and Drug Administration (FDA)	Not regulated.

Disclaimer

CRC cannot anticipate all conditions under which this information and its product, or the products of other manufacturers in combination with its product, may be used. It is the user's responsibility to ensure safe conditions for handling, storage and disposal of the product, and to assume liability for loss, injury, damage or expense due to improper use. The information contained in this document applies to this specific material as supplied. It may not be valid for this material if it is used in combination with any other materials. This information is accurate to the best of CRC Industries' knowledge or obtained from sources believed by CRC to be accurate. Before using any product, read all warnings and directions on the label. For further clarification of any information contained on this (M)SDS consult your supervisor, a health & safety professional, or CRC Industries.

FIGURE 3-8 (Continued)

SKILL DRILL 3-2 Identifying Information on a Safety Data Sheet

1. Once you have studied the information on the container label, find the MSDS for that material. Always check the revision date to ensure that you are reading the most recent update.
2. Note the chemical and trade names for the material, its manufacturer, and the emergency telephone number to call.
3. Find out why this material is potentially hazardous. It may be flammable, it may explode, or it may be poisonous if inhaled or touched with your bare skin. Check the **threshold limit values (TLVs)**. The concentration of this material in the air you breathe in your shop must not exceed these figures. There could be physical symptoms associated with breathing in harmful chemicals. Find out what will happen to you if you suffer overexposure to the material, either through breathing it in or by coming into physical contact with it. This will help you take safety precautions, such as eye, face, or skin protection; wearing a mask or respirator while using the material; or washing your skin afterwards.
4. Note the **flash point** for this material so that you know at what temperature it may catch fire. Also, note what kind of fire extinguisher you would use to fight a fire involving this material. The wrong fire extinguisher could make the emergency even worse.
5. Study the **reactivity** for this material to identify the physical conditions or other materials that you should avoid when using this material. It could be heat, moisture, or some other chemical.
6. Find out what special precautions you should take when working with this material. This will include personal protection for your skin, eyes, or lungs, as well as storage and use of the material.
7. Be sure to refresh your knowledge of your SDS from time to time. Be confident that you know how to handle and use the material and what action to take in an emergency, should one occur.

Electrical Hazards

Many people are injured by electricity in shops. Poor electrical safety practices can cause shocks and burns, as well as fires and explosions. Make sure you know where the electrical panels for your shop are. All circuit breakers and fuses should be clearly labeled so that you know which circuits and functions they control (FIGURE 3-10).

In the case of an emergency, you may need to know how to shut off the electricity supply to a work area or to your entire shop. Keep the circuit breaker and/or electrical panel covers closed to keep them in good condition, prevent unauthorized access, and prevent accidental contact with the electricity supply. It is important that you do not block or obstruct access to this electrical panel; keep equipment and tools well away so

FIGURE 3-9 Exhaust extraction hoses should be vented so that the exhaust gases are not drawn back indoors.

FIGURE 3-10 Electrical fuse panel—All fuses and switches should be clearly labeled with the circuits and functions they control.

emergency access is not hindered. In some localities, 3 ft (0.91 m) of unobstructed space must be maintained around the panel at all times. There should be enough electrical receptacles in your work area for all your needs. Do not connect multiple appliances to a single receptacle with a simple double adapter. If necessary, use a multi-outlet safety strip that has a built-in overload cut-out feature. Electric receptacles should be at least 3 ft (0.91 m) above floor level to reduce the risk of igniting spilled fuel vapors or other flammable liquids. Be sure that your shop has fire extinguishers rated to extinguish electrical fires and that you know where they are. Machines with high-voltage electric drive systems are becoming more common. Specific training and PPE is mandatory before a technician can work on a machine with high-voltage electric drive. *Never* work on live high-voltage equipment or machines.

Portable Electrical Equipment

If you need to use an extension cord, make sure it is made of flexible wiring—not the stiffer type of house wiring—and that it is fitted with a ground wire. The cord should be neoprene

covered, as this material resists oil damage. See **FIGURE 3-11** for an example of a proper electrical extension cord.

Always check it for cuts, abrasions, or other damage. Be careful how you place the extension cord, so that it does not cause a tripping hazard. Also, avoid rolling equipment or machines over it, as doing so can damage the cord. Never use an extension cord in wet conditions or around flammable liquids. Portable electric tools that operate at 240 volts are often sources of serious shock and burn accidents. Be particularly careful when using these items. Always inspect the cord for damage and check the security of the attached plug before connecting the item to the power supply. See **FIGURE 3-12** for an example of a damaged electrical cord. Use 110 volt or lower voltage tools if they are available. All electric tools must be equipped with a ground prong or double-insulated. If they are not, do not use them. Never use any high-voltage tool in a wet environment. Air-operated tools cannot give you an electric shock, because they operate on air pressure instead of electricity; so they are safer to use in a wet environment. High-voltage equipment like welders or kidney loop filters may have long cords to allow them to be used throughout a shop bay. These cords must be inspected carefully, and extra protection should be used for them anywhere there is a risk of damaging the insulation on them.

FIGURE 3-11 Extension cords—should be neoprene covered.

FIGURE 3-12 Never use an electrical cord if the insulation is damaged or cut.

SAFETY TIP

When the insulation has been cut or damaged on an electrical cord or the ground terminal is missing, it should be disposed of. Using electrical cords with damaged insulation or missing ground terminals may cause a shock, resulting in serious injury, fire, and even death.

Portable Shop Lights

Portable shop lights/droplights can be very useful tools to add light to a particular area or spot on the machine you are working on. Always make sure you follow the safety directions when using shop lights. They should have protective covers fitted to them to prevent accidentally breaking the lamp. If a lamp breaks, it can be an electrical hazard, particularly if a metal object comes in contact with exposed live electricity. For this reason, low-voltage lamps or lamps with fitted safety switches are often used in order to prevent accidental electrocution. Some shop lights are now cordless, particularly those with LEDs fitted as the light source. Cordless lights are a safe option because they isolate you from the high voltage. Electric droplights are a common source of shocks, especially if they are the wrong type for the purpose or if they are poorly constructed or maintained. All droplights should be designed in such a way that the electrical parts can never come into contact with the outer casing of the device. Such lights are called double-insulated. The bulb should be completely enclosed in a transparent insulating case or protected within a robust insulating cage. See **FIGURE 3-13** for an example of a proper droplight. The bulbs used in electric droplights are especially vulnerable to impact and must not be used without insulating cage protection. Incandescent bulbs present an extreme fire hazard if broken in the presence of flammable vapors or liquids and should not be used in repair shops. LED and fluorescent bulbs, while still hazardous, are much safer.

Fire Hazards

The danger of a fuel fire is always present in a repair shop. Most machines carry a fuel tank, often with large quantities of fuel on board, which is more than sufficient to cause a large, destructive, and potentially explosive fire. Take precautions to make sure you have the correct type and size of extinguishers on hand for a potential fuel fire. Make sure you clean up spills

FIGURE 3-13 All droplights should be properly protected.

immediately and avoid ignition sources, like sparks, when in the presence of flammable liquids or gases.

TECHNICIAN TIP

Fire danger is always present in shops, particularly because of the amount of flammable liquids and materials used in shops and machines. Always be aware of the potential for a fire, and plan ahead by thinking through the task you are about to undertake. Know where firefighting equipment is kept and how it works. Many shops require the use of a fire watch person when “hot work” is being performed (torchworking, welding, or grinding). The person on fire watch is to be on lookout for signs of fire in the area while hot work is being performed and for up to one hour afterward.

Fuel Vapor Liquid fuel vaporizes to different degrees, especially when spilled, and the vapor is generally easy to ignite. Because fuel vapor is invisible and heavier than air, it can spread unseen across a wide area, and a source of ignition can be quite some distance from the original spill. Fuel can even vaporize from the cloths or rags used to wipe up liquid spills. These materials should be allowed to dry in the open air, not held in front of a heater element. Any spark or naked flame, even a lit cigarette, can start an explosive fire.

Spillage Risks Spills frequently occur when technicians remove and replace fuel filters. They also occur during the removal of a fuel tank sender unit, which can be located on the side or top of the fuel tank, without first emptying the tank safely. Spills can also occur when fuel lines are damaged and are being replaced, when fuel systems are being checked, or when fuel is being drained into unsuitable containers. Avoid spills by following the manufacturer’s specified procedure when removing fuel system components. Also, keep a spill response kit nearby to deal with any spills quickly. Spill kits should contain absorbent material and barrier dams to contain moderate-sized spills.

Draining Fuel If there is a possibility of fuel spillage while working on a machine, then you should first remove the fuel safely. Do this only in a well-ventilated, level space, preferably outside in the open air. Make sure all potential sources of ignition have been removed from the area, and disconnect the battery on the machine. Do not drain fuel from a machine over an inspection pit. Make sure the container you are draining into is an approved fuel storage container (fuel retriever) and that it is large enough to contain all the fuel in the system being drained.

Using a Fuel Retriever The best practice for removing fuel from a machine’s fuel tank is to pump it out with a fuel transfer pump. Ensure that the receiving container is clean if the fuel is to be reused, and ensure that it doesn’t leak. Fuel transfer pumps can be electric or pneumatic. Check the service manual for details on how best to drain the fuel from the machine you are working on.

SAFETY TIP

Never weld anywhere near a gas tank or any kind of fuel line. Welding work on a tank is a job for specialists. An empty fuel tank can still contain vapor and therefore can be even more dangerous than one full of liquid fuel. Do not attempt to repair a tank yourself.

Toxic Dust Hazards

Toxic dust is any dust that may contain fine particles that could be harmful to humans or the environment. If you are unsure as to the toxicity of dust, then you should always treat it as toxic and take the precautions identified in the SDS or shop procedures. Brake and clutch dust are potential toxic dusts that repair shops must manage. The dust is made up of very fine particles that can easily spread and contaminate an area. One of the more common sources of toxic dust is inside drum brakes and manual transmission bell housings. It is a good idea to avoid all dust if possible, whether it is classified as toxic or not. If you do have to work with dust, never use compressed air to blow it from components or parts and always use PPE such as face masks, eye protection, and gloves. If you are cleaning up your area after a repair, do not dry sweep dust; instead, use a low-pressure wet cleaning method. Such methods include a soap and water solution used in a dedicated portable wash station, a low-pressure aerosol brake cleaning solution, or a pump spray bottle filled with water. You may also use a **HEPA** vacuum cleaner to collect dust and to clean equipment. HEPA stands for high-efficiency particulate absorption. HEPA filters can trap very small particles and prevent them from being redistributed into the surrounding air. After completing a servicing or repair task on a machine, dirt is often left behind. The materials present in this dirt usually contain toxic chemicals that can build up and cause health problems. To keep the levels of dirt to a minimum, clean up dirt immediately after the task is complete. The vigorous action of sweeping causes the dirt to rise; therefore, when sweeping the floor, use a soft broom that pushes, rather than flicks, the dirt forward. Create smaller dirt piles and dispose of them frequently. Another successful way of cleaning shop dirt is to use a water hose. The waste water must be caught in a settling pit and not run into a storm water drain.

Various tools have been developed to clean toxic dust from machine components. The most common one is the brake wash station. It uses an aqueous solution to wet down and wash the dust into a collection basin. The basin needs periodic maintenance to properly dispose of the accumulated sludge. This tool is probably the simplest way to effectively deal with hazardous dust because it is easy to set up, use, and store. Another such tool uses a vacuum cleaner that has a large cone attachment at the nozzle end. The base of the cone is open so that the brake assembly can fit into the cone. A compressed air nozzle, which is also attached to the inside of the cone, is used to loosen dirt particles. The particles are drawn into the cleaner via a very fine filter. Domestic vacuum cleaners are not suitable for this application because their filters are not fine enough to capture very small dust particles.

Used Engine Oil and Fluid Hazards

Used engine oil and fluids are liquids that have been drained from the machine, usually during servicing operations. Used oil and fluids will often contain dangerous chemicals and impurities and needs to be safely recycled or disposed of in an environmentally friendly way. **FIGURE 3-14** shows some of the equipment used to properly dispose of used oil. There are laws and regulations that

FIGURE 3-14 Used oil and fluids often contain harmful chemicals and contaminants and must be safely recycled and disposed of in an environmentally friendly way.

control the way in which they are to be handled and disposed of. The shop will have policies and procedures that describe how you should handle and dispose of used engine oil and fluids. Be careful not to mix incompatible fluids such as used engine oil and used coolant. Generally speaking, petroleum products can be mixed together. Follow your local, state, and federal regulations when disposing of waste fluids. Used engine oil is a hazardous material containing many impurities that can damage your skin. Coming into frequent or prolonged contact with used engine oil can cause dermatitis and other skin disorders, including some forms of cancer. Avoid direct contact as much as possible by always using gloves and other protective clothing, which should be cleaned or replaced regularly. Using a barrier-type hand lotion will also help protect your hands, as well as make cleaning them much easier. Also, follow safe work practices, which minimize the possibility of accidental spills. Keeping a high standard of personal hygiene and cleanliness is important so that you get into the habit of washing off harmful materials as soon as possible after contact. If you have been in contact with used engine oil, you should regularly inspect your skin for signs of damage or deterioration. If you have any concerns, see your doctor.

Identifying potential hazards is the most important part of safety in the workplace. You cannot protect yourself, or others, from hazards that you are not aware of. If you, or your shop management, don't identify the hazards in your workplace, they will not simply be ignored. Unless you identify hazards before an accident or mishap, hazards will tend to make themselves known in an unpleasant way.

► TECHNICIAN TIP

- Some machine components, including brake and clutch linings, contain asbestos, which, despite having very good heat properties, is toxic. Asbestos dust causes lung cancer. Complications from breathing in the dust may not show until decades after exposure.
- Airborne dust in the shop can also cause breathing problems such as asthma and throat infections.

- Never cause dust from machine components to be blown into the air. It can stay floating for many hours, meaning that other people will unknowingly breathe in the dust.
- Wear protective gloves whenever using solvents.
- If you are unfamiliar with a solvent or a cleaner, refer to the SDS for information about its correct use and applicable hazards.
- Always wash your hands thoroughly with soap and water after performing repair tasks on brake and clutch components.
- Always wash work clothes separately from other clothes so that toxic dust does not transfer from one garment to another.
- Always wear protective clothing and the appropriate safety equipment.

SAFETY TIP

Whenever using an atomizer with solvents and cleaners, make sure there is adequate exhaust ventilation. Wear appropriate breathing apparatus and eye protection.

► Hazard Assessment and Control Procedures

K03002

Develop a safe attitude toward your work. You should always think “safety first” and then act safely. Think ahead about what you are doing, and put in place specific measures to protect yourself and those around you. When you think ahead about what you are doing, you are conducting a hazard assessment. When you put into place specific measures to protect yourself and those around you, you are implementing control procedures. For example, you could ask yourself the following questions:

- What could go wrong?
- What measures can I take to ensure that nothing goes wrong?
- What PPE should I use?
- Have I been trained to use this piece of equipment?
- Is the equipment I’m using safe?

Answering these questions and taking appropriate action before you begin will help you work safely.

Most technicians working on **MORE** (mobile off-road equipment) machines will be required to complete a pre-job hazard assessment. This will be a standardized form with areas to fill in or check off to identify specific hazards related to the task being performed. The technician will also have to list ways to reduce risks and to list the types of PPE to be used. The forms (usually a pocket-sized card) will need to be carried with the technician and signed by their supervisor.

Industry Hazards Assessment and Control Processes

There are certain standard hazard assessment and control procedures and practices within industrial workplaces. For example, in the United States, the government regulator of safety in

the workplace is OSHA, which has a six-step process for hazard identification and assessment:

1. Collect existing information about workplace hazards.
2. Inspect the workplace for safety hazards.
3. Identify health hazards.
4. Conduct incident investigations.
5. Identify hazards associated with emergency and non-routine situations.
6. Characterize the nature of identified hazards, identify interim control measures, and prioritize the hazards to control.

OSHA also has a six-step process for hazards prevention and control:

1. Identify control options.
2. Select controls.
3. Develop and update a hazard control plan.
4. Select controls to protect workers during non-routine operations and emergencies.
5. Implement selected controls in the workplace.
6. Follow up to confirm that controls are effective.

Another common process for hazard assessment and control is called **operational risk management (ORM)**. This comprises a simple five-step process:

1. Identify the threats or hazards.
2. Assess the risk.
3. Analyze the risk control measures.
4. Make control decisions.
5. Implement risk controls.
6. Supervise and review.

The above-mentioned hazard assessment and control processes allow a workplace to have a standardized and consistent approach to workplace hazards and safety. Employees with a safe attitude follow these approaches to hazard assessment and control without thinking about it. For example, before beginning work on a fuel tank, you may place a portable fire extinguisher nearby, in case a fire were to break out. This is a great example of performing a hazard assessment and implementing appropriate control measures.

Continuous Hazards Assessment through Shop Safety Inspections

Shop safety inspections are valuable ways of identifying unsafe equipment, materials, or activities so that they can be corrected to prevent accidents or injuries. The inspection can be formalized by using inspection sheets to check specific items, or they can consist of general walk-arounds where you consciously look for problems that can be corrected.

Some of the common things to look for are items blocking emergency exits or walkways, poor safety signage, unsafe storage of flammable goods, tripping hazards, faulty or unsafe equipment or tools, missing fire extinguishers, clutter, spills, unsafe shop practices, and people not wearing the correct PPE. Formal and informal safety inspections should be held regularly. For example, an inspection sheet might be used weekly or

monthly to formally evaluate the shop, while informal inspections might be held daily to catch issues that are of a more immediate nature. During shop safety inspections, also look for hazardous practices committed by employees. Here are some items to pay attention to in your workplace.

Proper Ventilation

Proper ventilation is required for working in the shop area. The key to proper ventilation is to ensure that any task or procedure that may produce dangerous or toxic fumes are recognized so that measures can be put in place to provide adequate ventilation. Ventilation can be provided by natural means, such as by opening doors and windows to provide air flow for low-exposure situations. However, in high-exposure situations, such as machines running in the shop, a mechanical means of ventilation is required; an example is an exhaust extraction system. Areas where parts are being cleaned or areas where solvents and chemicals are used should also have good general ventilation, and if required, additional exhaust hoods or fans should be installed to remove dangerous fumes. In some cases, such as when spraying paint, it may be necessary to use a personal respirator in addition to proper ventilation.

► TECHNICIAN TIP

Before beginning a task, research the proper ventilation procedure for working within the shop area. Use the correct ventilation equipment and procedures for the activities you are working on within the shop area.

Lifting

Whenever you lift something, there is always the possibility of injury; however, by lifting correctly, you reduce the chance of something going wrong. Before lifting anything, you can reduce the risk of injury by breaking down the load into smaller quantities, asking for assistance if required, or possibly using a mechanical device to assist you when you lift. If you must bend down to lift something, you should bend your knees to lower your body; do not bend over with straight legs, because this can damage your back (**FIGURE 3-15**). Place your feet about shoulder width apart and lift the item by straightening your legs while keeping your back as straight as possible.

SAFETY TIP

When lifting objects repeatedly, use a **back brace**. When lifting heavy or large objects get someone else to help.

Housekeeping and Orderliness

Good housekeeping is about always making sure the shop and your work surroundings are neat and kept in good order. Trash and liquid spills should be quickly cleaned up, tools need to be cleaned and put away after use, spare parts need to be stored correctly, and generally everything needs to have a safe place to be kept. You should carry out good housekeeping practices

FIGURE 3-15 Prevent back injuries when lifting heavy objects by crouching, with your legs shoulder width apart, standing as close to the object as possible, and positioning yourself so that the center of gravity is between your feet. Use your legs to lift the object, not your back.

while working, not just after a job is completed. For example, get rid of trash as it accumulates, clean up spills when they happen, and put tools away when you are finished working with them. It is also good practice to periodically perform a deep clean of the shop so that any neglected areas are taken care of.

Slip, Trip, and Fall Hazards

Slip, trip, and fall hazards are ever present in the shop, and they can be caused by trash, tools and equipment, or liquid spills being left lying around. Always be on the lookout for hazards that can cause slips, trips, or falls. Floors and steps can become slippery, so they should be kept clean and have anti-slip coatings applied to them. High-visibility strips with anti-slip coatings can be applied to the edge of step treads to reduce the hazard. Clean up liquid spills immediately and mark the area with wet floor signs until the floor is dry. Make sure the shop has good lighting so that hazards are easy to spot, and keep walkways clear from obstruction. Think about what you are doing, and make sure the work area is free of slip, trip, and fall hazards as you work.

Most government legislation requires workers to wear fall-arrest harnesses if working at heights of 10 ft or more in an area that has no barricades or railings. There are many workplaces that have lower height thresholds for implementation of working at heights, such as 6 ft. There will be specific training required for working at heights to educate workers on things like proper harness usage, acceptable tie-off points, and acceptable documentation. Many situations will see a technician working at heights on a MORE machine. Always inspect the integrity of the tie-off points before connecting a fall-arrest harness to them.

Working on MORE machines often requires a technician to work on a jobsite. For construction sites and quarries, uneven ground and slippery conditions will introduce many slip and trip hazards. Extra caution needs to be taken when working on machines outside of the shop environment.

The safest workplaces have a high level of commitment from the employer by having standardized safety processes in

place, proper safety equipment, as well as employees committed to safety. Safety is a continuous process that requires constantly assessing new hazards and implementing effective controls to maintain a safe working environment.

► Safety Regulations, Procedures, and Occupational Safety Standards

K03003, A03002

Safety regulations, procedures, and standards are important because they provide consistency by requiring everyone to follow the same set of rules governing their actions related to safety. Safety regulations, procedures, and standards also provide a way to share information about how to avoid past accidents and mishaps. This is done by including lessons learned from past accidents and mishaps at your workplace, or others, in the safety regulations, procedures, and standards of your shop. Most people can imagine how nonsensical it would be if every employee were injured performing the same repair procedure on a piece of equipment simply because no one communicated how to avoid the hazard that caused the injury. Safety regulations, procedures, and standards are effective at preventing accidents and mishaps because they communicate how to avoid and minimize certain hazards and injuries based on lessons learned from previous accidents and mishaps.

Next we will talk about three types of safety regulations, procedures, and standards:

- government and industry regulations, procedures, and standards
- shop policies, procedures, and standards
- equipment manufacturer policies, procedures, and standards.

Government and Industry Regulations, Procedures, and Standards

Most countries have government and industry entities that regulate certain aspects of safety and environmental issues in the workplace. The regulations, rules, processes, procedures, and standards set by government entities are usually a matter of law. Violations of these regulations can result in civil and sometimes criminal penalties for employees and the employer. Employees and managers should be familiar with government safety regulations as they apply to their workplace in order to prevent penalties – but most importantly to keep everyone safe. In addition to government regulators, many industries have entities that may set safety-related rules, regulations, and recommended practices. Some examples of these are the [Society of Automotive Engineers \(SAE\)](#) and the [National Institute for Automotive Service Excellence \(ASE\)](#). While they do not usually carry the force of law, these entities can better determine how to apply safety and government safety regulations to your specific workplace. In the United States, there are two primary government agencies that you will need to become familiar with: [OSHA](#) and the [EPA](#).

OSHA is a U.S. government agency that was created to provide national leadership in occupational safety and health. It finds the most effective ways to help prevent worker fatalities and workplace injuries and illnesses. OSHA has the authority to conduct workplace inspections and, if required, fine employers and workplaces if they violate OSHA regulations and procedures. For example, a fine may be imposed on the employer or workplace if a worker is electrocuted by a piece of faulty machinery that has not been regularly tested and maintained.

EPA stands for the Environmental Protection Agency. This federal government agency deals with issues related to environmental safety. The EPA (Environmental Protection Agency) conducts research and monitoring, sets standards, and can hold employees and companies legally accountable to keep the environment protected. Shop activities will need to comply with EPA laws and regulations by ensuring that waste products are disposed of in an environmentally responsible way, chemicals and fluids are correctly stored, and work practices do not contribute to damaging the environment. In addition, specific industries may have further regulatory entities they must answer to. For example, in the mining industry in the United States, [MSHA \(Mine Safety and Health Administration\)](#) sets additional rules and regulations that effect MORE (mobile off-road equipment) technicians. While the examples in this chapter refer to OSHA, MSHA, and the EPA, most countries have equivalent organizations. If you are in a geographic region outside of North America, you should check with your local government authorities for the appropriate regulations that apply to your location. Both OSHA and the EPA publish useful information related to safety and environmental friendliness in the workplace. If you are looking for information about safety or the environment in the workplace, the OSHA and EPA websites are a valuable source.

► TECHNICIAN TIP

Most workplaces are required to form a joint health and safety committee. The number of members is dependent on the number of employees that work on site. The committee is made up of supervisory staff and employees and is mandated to hold regular meetings to discuss health and safety concerns and put action plans in place to remedy and prevent problems.

Shop Policies, Procedures, and Standards

Shop policies and procedures are a set of documents that outline how tasks and activities in the shop are to be conducted and managed. They also ensure that the shop operates according to OSHA and EPA laws and regulations. A **policy** is a guiding principle that sets the shop direction, while a **procedure** is a list of the steps required to get the same result each time a task or activity is performed. An example of a policy would be an OSHA document for the shop that describes how the shop complies with legislation. An example of a procedure would be a document that describes the steps required to safely use

a commercial vehicle hoist. Each shop will have its own set of policies and procedures and a system in place to make sure the policies and procedures are regularly reviewed and updated. Regular reviews ensure that new policies and procedures are developed and that old ones are modified in case something has changed. For example, if the shop moves to a new building, then a review of policies and procedures will determine which ones of them relate to the new shop, its layout, and equipment. In general, the policies and procedures are written to guide shop practice; help ensure compliance with laws, statutes, and regulations; and reduce the risk of injury. Always follow your shop policies and procedures to reduce the risk of injury to your coworkers and yourself and to prevent damage to property. It is everyone's responsibility to know and follow the rules. Locate the general shop rules and procedures for your workplace. Look through the contents or index pages to familiarize yourself with the contents. Discuss the policy and the shop rules and procedures with your supervisor. Part of the safety policies in most large shops are procedures and requirements for reporting hazards. It is the responsibility of all workers in a shop to identify and report hazards that haven't been previously reported. Once reported, the company must take action to reduce risks related to the hazard. Ask questions to ensure that you understand how the rules and procedures should be applied and your role in making sure they are followed.

► TECHNICIAN TIP

Machines often can't be brought to a repair shop and must be repaired on site. The technician assigned to the repair may be required to attend a site orientation seminar before being allowed to enter the customer's workplace. This seminar will make the technician aware of all site-specific safety policies, including information about fire escapes and PPE requirements and locations for first aid kits.

Equipment Manufacturer Policies, Procedures, and Standards

When you need information about a specific piece of equipment or machinery, you should consult the equipment manufacturer's information. Equipment manufacturers publish **operating manuals**, **repair and maintenance manuals**, and **technical and safety bulletins**. The manufacturer's information should be considered the most correct and authoritative information regarding the safe and proper operation, repair, and maintenance of that specific piece of equipment. Prior to operating, or repairing, an unfamiliar piece of equipment, it is good practice to consult the applicable manufacturer's operating or maintenance and repair manual. When reviewing the manufacturer's manual, pay attention to safety-related messages like danger, warning, cautions, and notices. The manufacturer knows better than anyone else how to safely and properly operate their equipment. It has often been said that workplace safety regulations, policies, and procedures are "written in blood." This means that they have been written and revised many times due to lessons learned from past accidents that have resulted in serious injuries and death to employees. It is much easier to learn from the past

mistakes of others by following current workplace safety rules than by learning from your own mistakes.

► Emergency Actions and Procedures

K03004, A03001

If an accident or mishap occurs, it is important for both employees and the employer to know what to do. An accident or mishap can quickly become an emergency if not handled properly. An emergency is a serious, unexpected, and often dangerous situation requiring immediate attention. An emergency can cause serious equipment damage, personal injury, or even death if not properly addressed. It is critical that your shop educate all employees on how to handle emergency situations they may encounter. It is also critical that your shop has the appropriate emergency information and supplies readily available in a prominent location and that all employees know where these items are. An emergency situation can escalate quickly; it is vital that employees know where emergency items and instructions are before an emergency occurs. During an emergency, time lost attempting to locate fire extinguishers, emergency eye wash stations, emergency equipment shut down controls, first aid kits, and first aid instructions can result in further equipment damage or injury to personnel. In the next few paragraphs, we will discuss some common emergency situations and actions.

Equipment Emergencies

An equipment emergency can result in damage to equipment, shop facilities, hazardous material spills, and injury to personnel if not properly addressed. Some examples of equipment emergencies are a runaway diesel engine, malfunctioning welding equipment, shop crane failure, air compressor failures, leaking oil storage containers, and equipment fires. The best action taken to address equipment emergencies is prevention. Ensure that all equipment is maintained, inspected, and working properly. Remove malfunctioning equipment from service promptly. Ensure all safety and emergency devices are installed and work properly on equipment. Ensure employees know where emergency shutdown controls are, and ensure they are clearly visible. However, when an equipment emergency does occur, know how to address it by following these simple steps:

- Is the situation dangerous to people in the area?
 - If needed, evacuate all people in the area that could be effected.
- Is the situation dangerous to me?
 - If it is dangerous for me to enter the area, evacuate and contact emergency services.
- How do I stop the situation from getting worse?
 - If available, and safe to do so, use the emergency shutdown control at the equipment.
 - If not, attempt to shut down the equipment at the main electrical panel.
 - If possible, apply control measures to prevent further damage and risk to equipment.

When possible, we want to limit the damage caused by equipment emergencies. The most important action is to prevent injury to personnel. If you can safely address an equipment emergency, then do so. If addressing the equipment emergency would risk your safety, or the safety of others, evacuate and contact emergency services.

First Aid Emergencies

The following information is designed to acquaint you with basic first aid principles and the importance of first aid training courses. You will find general information about how to take care of someone who is injured. However, this information is only a guide. It is not a substitute for training or professional medical assistance. Always seek professional advice when tending to an injured person.

First aid is the immediate care given to an injured or suddenly ill person. Learning first aid skills is valuable in the workplace in case an accident or medical emergency arises. First aid courses are available through many organizations, such as the Emergency Care and Safety Institute (ECSI). It is strongly advised that you seek out a certified first aid course and become certified in first aid. The following information highlights some of the principles of first aid. In the event of an accident, the possibility of injury to the rescuer or further injury to the victim must be assessed. The first step is to survey the scene. While doing this, try to determine what happened, what dangers may still be present, and the best actions to take. Remove the injured person from a dangerous area only if it is safe for you to do so. When dealing with electrocution or electrical burns, make sure the electrical supply is switched off before attempting any assistance.

Always perform first aid techniques as quickly as is safely possible after an injury. When breathing has ceased or when the heart has stopped, brain damage can occur within four to six minutes. The degree of brain damage will increase with each passing minute, so make sure you know what to do, and do it quickly.

► TECHNICIAN TIP

There are three important rules of first aid:

1. Know what you must not do.
2. Know what you must do.
3. If you are not sure what procedures to follow, send for trained medical assistance.

First Aid Principles

Prompt care and treatment prior to the arrival of emergency medical assistance can sometimes mean the difference between life and death. The goals of first aid are to make the immediate environment as safe as possible, preserve the life of the patient, prevent the injury from worsening, prevent additional injuries from occurring, protect the unconscious, promote recovery, comfort the injured, prevent any delay in treatment, and provide the best possible care for the injured person. When attending

to an injured victim, always send for assistance. Make sure the person who stays with the injured victim is more experienced in first aid than the messenger. If you are the only person available, request medical assistance as soon as reasonably possible. When you approach the scene of an accident or emergency, do the following:

1. **Danger:** Make sure there are no other dangers, and assist only if it is safe to do so.
2. **Response:** Check to see if the victim is responsive and breathing. If responsive, ask the victim if he or she needs help. If the victim does not respond, he or she is unresponsive.
3. Have a bystander call 911. If alone, call 911 yourself (or, if in another country, the relevant emergency assistance phone number).
4. If the victim is unresponsive and not breathing, place your hands in the center of the victim's chest and provide 30 chest compressions hard and fast (**FIGURE 3-16**).
5. Tilt the victim's head back and lift the chin to open the airway. Give one rescue breath lasting one second, take a normal breath for yourself, and then give the victim another breath lasting one second. Each rescue breath should make the victim's chest rise.
6. Repeat the compression and breath cycles until an **automated external defibrillator (AED)** is available or EMS (emergency medical service) personnel arrive (**FIGURE 3-17**).
7. Once an AED arrives, expose the victim's chest and turn on the AED. Attach the AED pads. Ensure that no one touches the victim. Follow the audio and visual prompts from the AED. If no shock is advised, resume CPR (cardiopulmonary resuscitation) immediately (five sets of 30 compressions and two breaths). If a shock is advised, do not touch the victim, and give one shock. Or, shock as advised by AED. Immediately resume 30 compressions and two breaths.

Bleeding

A wound that is severely bleeding is serious. If the bleeding is allowed to continue, the victim may collapse or die. Bleeding is divided into two categories: external and internal. **External**

FIGURE 3-16 Chest compressions.

FIGURE 3-17 The use of an AED is taught in all certified CPR training classes.

bleeding is the loss of blood from an external wound where blood can be seen escaping. **Internal bleeding** is the loss of blood into a body cavity from a wound with no obvious sign of blood. Before providing first aid, make sure you are not exposed to blood. Wear latex gloves or an artificial barrier. Lay the victim down, then apply a gauze pad and direct pressure to the wound (**FIGURE 3-18**). Apply a pressure bandage over the gauze. If blood soaks through the bandage, apply additional dressings and pressure bandage (**FIGURE 3-19**). Call 911 if bleeding cannot be controlled. Give nothing by mouth to the victim and seek medical aid immediately. If an object punctures the victim's skin and becomes embedded in the victim's body, do not attempt to remove the object. Stabilize the object with a bulky dressing. Seek medical care immediately. If the injured person has internal bleeding, it may not be immediately obvious. Symptoms of internal bleeding are bruising, a painful or tender area, coughing frothy blood, vomiting blood, stool that is black or contains bright red blood, and passing blood with urine. To assist an injured victim with internal bleeding, lay the victim down, loosen tight clothing, give nothing by mouth, and seek medical aid immediately.

FIGURE 3-18 Apply a gauze pad, and direct pressure to the wound.

FIGURE 3-19 If blood soaks through the bandages, apply additional bandages on top of the existing ones.

SAFETY TIP

During an emergency, never remove existing bandages and dressings simply because they are bleeding through. Always apply the new ones on top of the existing bandages. Removing existing bandages from an open wound will cause it to reopen and result in more bleeding.

Eye Injuries

Foreign objects can become embedded in the eye, or chemicals can splash into the eye. If an object penetrates and becomes embedded in the eye, do not attempt to remove it. Lay the victim down, stabilize the object with a bulky dressing or clean cloths, ask the victim to close the other eye, and call 911 (or the relevant emergency assistance phone number) (**FIGURE 3-20**). If an object is loose on the surface of the eye, pull the upper lid over the lower lid. Hold the eyelid open and gently rinse with water. Examine the lower lid by pulling it down gently.

FIGURE 3-20 If an object penetrates and becomes embedded in the eye, stabilize the object with a bulky dressing, clean cloths, or a small foam cup. Then seek immediate medical attention. *Do not* remove the object.

If you can see the object, remove it with a moistened sterile gauze, a clean cloth, or a moistened cotton swab. Examine the underside of the upper lid by grasping the lashes of the upper lid and rolling the lid upward over a cotton swab. If you can see the object, remove it with a moistened sterile gauze or a clean cloth (**FIGURE 3-21**). If some chemical splashes into the eyes, you may be able to flush it out using an eye wash station (**FIGURE 3-22**). Hold the eye wide open and flush with warm water for at least 20 minutes, continuously and gently. Irrigate from the nose side of the eye toward the outside to avoid flushing material into the other eye. Loosely bandage the eyes with wet dressings. Call 911 (or the relevant emergency assistance phone number).

Eyewash Stations and Emergency Showers

Hopefully you will never need to use an eye wash station or emergency shower. The best treatment is prevention, so make sure you wear all the PPE required for each specific task to avoid injury. Eye wash stations are used to flush the eye with clean water or sterile liquid if you get foreign liquid or particles

FIGURE 3-21 Locate and remove a foreign object from the eye.

FIGURE 3-22 Emergency eyewash station: Flush out the eye to prevent chemical burns at an emergency eye wash station.

in your eye. There are different types of eye washers; the main ones are disposable eye wash packs and eye wash stations. Some emergency or deluge showers also have an eye wash station built in. When someone gets chemicals in their eyes, they typically need assistance in reaching the eye wash station. Take their arm and lead them to it. They may not want to open their eyes even in the water, so encourage them to use their fingers to pull their eyelids open. If a chemical splashed in their eyes, encourage them to rinse their eyes for 20 minutes. While they are rinsing their eyes, call for medical assistance.

Fractures

A fracture is a broken or cracked bone. Always seek medical care for all fractures. There may be symptoms you are not aware of that may make the injury more complex than first thought. There are three types of bone fractures: A **simple fracture** involves no wound or internal or external bleeding; an **open fracture** involves bleeding or the protrusion of bone through the skin; and a **complicated fracture** involves penetration of a bone into a vital organ. The symptoms of a fracture include hearing a snapping noise when the injury occurred, pain or tenderness at or near the injury, inability to move the limb, loss of strength in the limb, shortening of the limb or an abnormally shaped limb, swelling and/or bruising around the area, and a grinding noise if the limb is moved. Allow the victim to support the injured area in the most comfortable position. Stabilize the injured part with your hands or a splint to prevent movement. If the injury is an open fracture, do not push on any protruding bone. Cover the wound and exposed bone with a dressing. Apply ice or a cold pack if possible to help reduce swelling or pain. Call 911 (or the relevant emergency assistance phone number) for any open fractures or large bone fractures. Do not move the victim unless there is an immediate danger. Be aware of the onset of **shock**, which may present as the victim vomiting or fainting. Shock is when the body's tissues do not receive enough oxygenated blood.

Sprains, Strains, and Dislocations

When a joint has been forced past its natural range of movement, or a muscle or ligament has been overstressed or torn, a sprain, strain, or dislocation may occur. A **sprain** occurs when a joint is forced beyond its natural movement limit. This causes stretching or tearing in the ligaments that hold the bones together. The symptoms of a sprain include pain and loss of limb function, with swelling and bruising present. When a sprain occurs, apply covered ice packs every 20 minutes, elevate the injured limb, and apply an elastic compression bandage to the area and beyond the affected area. You should always treat a sprain as a fracture until medical opinion says otherwise.

A **strain** is an injury caused by the overstretching of muscles and tendons. Symptoms of a strain are sharp pain in the area immediately after the injury occurs, increased pain when using the limb, or tenderness over the entire muscle. The muscle may also have an indentation at the strain's location. When

a strain occurs, have the victim rest, elevate the injured limb, apply covered ice packs every 20 minutes, and apply an elastic compression bandage. A **dislocation** is the displacement of a joint from its normal position; it is caused by an external force stretching the ligaments beyond their elastic limit. Symptoms of a dislocation are pain or tenderness around the area, inability to move the joint, deformity of the joint, and swelling and discoloration over the joint. If a dislocation occurs, try to immobilize the limb and seek medical attention. Do not try to put the joint back in place.

Burns and Scalds

Burns are injuries to body tissues, including skin, that are caused by exposure to heat, chemicals, and radiation. Burns are classified as either superficial, partial thickness, or full thickness. Superficial burns, or **first-degree burns**, show reddening of the skin and damage to the outer layer of skin only (**FIGURE 3-23**). Partial-thickness burns, or **second-degree burns**, involve blistering and damage to the outer layer of skin (**FIGURE 3-24**). Full-thickness burns, or **third-degree burns**, involve white or

FIGURE 3-23 First-degree burn.

FIGURE 3-24 Second-degree burn.

FIGURE 3-25 Third-degree burn.

blackened areas and include damage to all skin layers and underlying structures and tissues (**FIGURE 3-25**). Burns can be caused by excessive heat, such as from fire; friction, such as from a rope burn; radiation, such as from a welding flash or a sunburn; chemicals, including acids and bases; or electricity, such as from faulty appliances. Scalds are injuries to the skin caused by exposure to hot liquids and gases. The effects of burns and scalds can include permanent skin and tissue damage, blisters caused by damage to surface blood vessels, severe pain, and shock. Remove the victim from any danger. If clothing is burning, have the victim roll on the ground using the “stop, drop, and roll” method. Smother the flames with a fire blanket or douse the victim with water. For minor burns, cool the burn with cool water until the body part is pain free. After the burn has cooled, apply antibiotic ointment. Do not apply lotions or aloe vera. Cover the burn loosely with a dry, nonstick, sterile, or clean dressing. Do not break any blisters. Give an over-the-counter pain medication such as ibuprofen. Seek medical care. Any large or third-degree burn must be treated by a qualified medical practitioner. Serious burns include skin that is blackened, whitened, or charred; a burn that is larger than three-quarters of an inch (2 cm) in diameter; or a burn that is in the airway or on the face, hands, or genitals. When presented with such burns, call 911 immediately.

Fire Emergencies

A fire is one of the most dangerous situations you may encounter in your shop. A fire can get out of control quickly. That is why it is important to know what to do in case of a fire emergency. If a fire occurs in your shop, clear everyone in the area and sound the alarm. Attempt to extinguish the fire only if it is small and under control. If you have any doubt about your ability to extinguish the fire quickly, evacuate the area and call emergency services.

Extinguishing Fires

Three elements must be present at the same time for a fire to occur: fuel, oxygen, and heat. The secret of firefighting involves the removal of at least one of these elements, usually the oxygen

or the heat, to extinguish the fire. For example, a fire blanket when applied correctly removes the oxygen, while a water extinguisher removes heat from the fire. In the shop, fire extinguishers are used to extinguish most small fires. Never hesitate to call the fire department if you cannot extinguish a fire safely.

Fire Classifications In North America, there are five classes of fire:

- Class A fires involve ordinary combustibles such as wood, paper, or cloth.
- Class B fires involve flammable liquids or gaseous fuels.
- Class C fires involve electrical equipment.
- Class D fires involve combustible metals such as sodium, titanium, and magnesium.
- Class K fires involve cooking oil or fat.

Fire Extinguisher Types Fire extinguishers are marked with pictograms that depict the types of fires that the extinguisher is approved to fight (**FIGURE 3-26**):

- Class A: Green triangle
- Class B: Red square
- Class C: Blue circle
- Class D: Yellow pentagram
- Class K: Black hexagon

Fire Extinguisher Operation Always sound the alarm before attempting to fight a fire. If you cannot fight the fire safely, leave the area while you wait for backup. You will need to size up the fire before you make the decision to fight it with a fire extinguisher by identifying what sort of material is burning, the extent of the fire, and the likelihood of it spreading. To operate a fire extinguisher, follow the acronym for fire extinguisher use, PASS:

- Pull.
- Aim.

FIGURE 3-26 Fire Extinguisher—Type Labels—Fire extinguishers often include a shape as well as a letter to denote its classification.

- Squeeze.
- Sweep.

Pull out the pin that locks the handle at the top of the fire extinguisher to prevent accidental use (**FIGURE 3-27A**). Carry the fire extinguisher in one hand, and use your other hand to aim the nozzle at the base of the fire (**FIGURE 3-27B**). Stand about 8–12 ft (2.4–3.7 m) away from the fire and squeeze the handle to discharge the fire extinguisher (**FIGURE 3-27C**). Remember that if you release the handle on the fire extinguisher, it will stop discharging. Sweep the nozzle from side to side at the base of the fire (**FIGURE 3-27D**).

Continue to watch and never turn your back to a fire. Although it may appear to be extinguished, it may suddenly reignite. If the fire is indoors, you should be standing between the fire and the nearest safe exit. If the fire is outside, you should stand facing the fire with the wind on your back so that the smoke and heat are being blown away from you. If possible, get an assistant to guide you and inform you of the fire's progress. Again, make sure you have a means of escape, should the fire get out of control. When you are certain that the fire is out, report it to your supervisor. Also, report what actions you took to put out the fire. Once the circumstances of the fire have been investigated and your supervisor or the fire department has given you the all clear, clean up the debris and submit the used fire extinguisher for inspection.

Fire Blankets Fire blankets are designed to smother a small fire and are effective at putting out a fire on a person. They are also used in situations where a fire extinguisher could cause damage. For example, if there is a small fire under the hood of a machine, a fire blanket might be able to smother the fire without running the risk of getting fire extinguisher powder down the intake system. Obtain a fire blanket and study the how-to-use instructions on the packaging. If instructions are not provided, research how to use a fire blanket or ask your supervisor. You may require instruction from an authorized person in using the fire blanket. If you do use a fire blanket, make sure you return the blanket for use or, if necessary, replace it with a new one.

The most important things that your employer can do to ensure that emergencies result in the least amount of equipment damage and injuries is to ensure that the shop has the proper equipment for emergencies, that employees have been trained properly, and that employees are given the proper information on how to handle emergencies. The most important thing that you can do is know how to handle emergencies before they occur. If you do not know how to handle an emergency before it occurs, you will not know how to handle the emergency when it happens. Know where the location of emergency devices such as fire extinguishers, fire alarms, spills kits, first aid kits, and emergency eye wash station are in your shop. Know how administer basic first aid during emergencies. Know where important emergency information is, such as SDS for hazardous materials. Knowing how to handle emergencies before they occur could save your life or the life of a coworker.

FIGURE 3-27 To operate a fire extinguisher, follow PASS: **A.** Pull, **B.** Aim, **C.** Squeeze, **D.** Sweep.

► Selection and Use of Personal Protective Equipment (PPE)

K03005, S03001, S03002

PPE is equipment used to block the entry of hazardous materials into the body or to protect the body from injury. PPE includes clothing, shoes, safety glasses, hearing protection, masks, and respirators (**FIGURE 3-28**).

Employee and Employer Responsibilities in Selecting and Using PPE

Employers are responsible for providing most of the PPE needed in the workplace. During new-hire orientation and onboarding, you may be advised that you are required to purchase certain PPE before starting work, such as steel-toe shoes and safety glasses. Employers are also responsible for providing training to employees on the proper PPE to wear or use for each work task and machine. This information should also be published in your shop safety policies and procedures. While it is your

FIGURE 3-28 PPE includes clothing, shoes, safety glasses, hearing protection, dust masks, respirators, and fall protection harnesses.

employer's responsibility to provide the proper PPE and inform you about how and where to use it, it is the employee's responsibility to ensure they wear or use the correct PPE when needed.

An employee who is injured due to failure to use the proper PPE may be subject to disciplinary actions. Furthermore, most employers do not want to employ a person who has a consistent disregard for their own and others' safety.

Selecting the Appropriate PPE

Before you undertake any activity, think about all potential hazards and select the correct PPE based on the risk associated with the activity. For example, if you are going to change hydraulic brake fluid, put on some gloves to protect your skin from chemicals.

As you go through this chapter, you will learn how to identify the correct PPE for a given activity and how to wear it safely. The PPE you use must fit correctly and be appropriate for the task you are undertaking. For example, if the task requires you to wear eye protection and specifies that you should use a full-face shield, do not try to cut corners and only wear safety glasses. You also need to make sure the PPE you are using is worn correctly. For example, a hairnet that does not capture all your hair is not protecting you adequately.

Types and Uses of PPE

There are many types and uses of PPE. But they all have one thing in common: to prevent injury to the user. It is vital that you are familiar with the different types and uses of PPE. You will not always be told what type of PPE is best for a given situation. By knowing the various types of PPE and their uses, you can choose the best PPE for the task.

Protective Clothing

Protective clothing includes items like shirts, pants, shoes, and gloves. These items are your first line of defense against injuries and accidents and must be worn when performing any work. Always make sure protective clothing is kept clean and in good condition. You should replace any clothing that is not in good condition, since it is no longer able to fully protect you.

► TECHNICIAN TIP

Each shop activity will require specific clothing depending on its nature. Research and identify what specific type of clothing is required for every activity you undertake. Wear appropriate clothing for various activities according to the shop's policy and procedures.

Work Clothing Always wear appropriate work clothing. Whether this is a one-piece coverall/overall or a separate shirt and pants, the clothes you work in should be comfortable enough to allow you to move, without being loose enough to catch on machinery. The material must be flame retardant and strong enough that it cannot be easily torn. A flap must cover buttons or snaps. If you wear a long-sleeve shirt, the cuffs must be close fitting, without being tight. Pants should not have cuffs, so that hot debris cannot become trapped in the fabric.

Taking Care of Clothing Always wash your work clothes separately from your other clothes. Start a new working day with clean work clothes, and change out of contaminated clothing as

soon as possible. It is a good idea to keep a spare set of work clothes in the shop in case a toxic or corrosive fluid is spilled on the clothes you are wearing.

Footwear

The proper footwear provides protection against chemicals, cuts, abrasions, slips, and items falling on your feet. The soles of your shoes must be acid and slip resistant, and the uppers must be made from a puncture-proof material such as leather. MORE technicians almost always wear safety shoes with a steel cap to protect the toes (**FIGURE 3-29**). Always wear shoes that comply with your local shop standards.

Headgear

Headgear includes items like hairnets, caps, and hard hats. They help protect you from getting your hair caught in rotating machinery and protect your head from knocks or bumps. For example, your hard hat can protect you from bumping your head on a machine when the machine is raised on a hoist. It is also good practice to wear a cap to hold longer hair in place and to keep it clean when working under a machine. Some caps are designed specifically with additional padding on the top to provide extra protection against bumps.

Hand Protection

Hands are a very complex and sensitive part of the body, with many nerves, tendons, and blood vessels. They are susceptible to injury and damage. Nearly every activity performed on machines requires the use of your hands, all of which put you at risk of injury. Whenever possible, wear gloves to protect your hands. There are many types of gloves available, and their applications vary greatly. It is important to wear the correct type of glove for the various activities you perform.

Chemical Gloves Heavy-duty and impenetrable chemical gloves should always be worn when using solvents and cleaners. They should also be worn when working on batteries. Chemical gloves should extend to the middle of your forearm to reduce the risk of chemicals splashing onto your skin (**FIGURE 3-30**).

FIGURE 3-29 Safety footwear protects against chemicals, cuts, abrasions, slips, and items falling on your feet.

FIGURE 3-30 Chemical gloves should extend to the middle of your forearms to reduce the risk of chemical burns to your skin.

Always inspect chemical gloves for holes or cracks before using them, and replace them when they become worn. Some chemical gloves are also slightly heat resistant. This type of chemical glove is suitable for use when removing radiator caps and mixing coolant.

Leather Gloves Leather gloves will protect your hands from burns when welding or handling hot components (**FIGURE 3-31**). You should also use them when removing steel from a storage rack and when handling sharp objects. When using leather gloves for handling hot components, be aware of the potential for heat buildup. **Heat buildup** occurs when the leather glove can no longer absorb or reflect heat, and heat is then transferred to the inside of the leather glove. At this point, the leather gloves' ability to protect you from the heat is reduced, so you will need to stop work, remove the leather gloves, and allow them to cool down before continuing to work. Also, avoid picking up very hot metal with leather gloves, because it causes the leather to harden, making it less flexible during use. If very hot metal must be moved, it would be better to use an appropriate pair of pliers.

Light-Duty Gloves Light-duty gloves should be used to protect your hands from exposure to greases and oils (**FIGURE 3-32**). Light-duty gloves are typically disposable and can be made from a few

FIGURE 3-31 Leather gloves will protect your hands from burns when welding or when handling hot parts.

FIGURE 3-32 Light-duty gloves should be used to protect your hands from grease and oils.

FIGURE 3-33 Cloth gloves work well in cold temperatures, so that cold metal tools do not stick to your skin.

different materials, such as nitrile, latex, and even plastic. Some people have allergies to these materials. If you have an allergic reaction when wearing these gloves, try using a glove made from a different material.

General-Purpose Cloth Gloves Cloth gloves are designed to be worn in cold temperatures, particularly during winter, so that cold tools do not stick to your skin (**FIGURE 3-33**). Over time, cloth gloves will accumulate dirt and grime, so you will need to wash them regularly. Regularly inspect cloth gloves for damage and wear, and replace them when required. Cloth gloves are not an effective barrier against chemicals or oils, so never use them for that purpose.

Barrier Cream **Barrier cream** looks and feels like a moisturizing cream, but it has a specific formula to provide extra protection from chemicals and oils. Barrier cream prevents chemicals from being absorbed into your skin and should be applied to your hands before you begin work (**FIGURE 3-34**). Even the slightest exposure to certain chemicals can lead to dermatitis, a painful skin irritation. Never use a standard moisturizer as a replacement for proper barrier cream. Barrier cream also makes it easier to clean your hands because it can prevent fine particles from adhering to your skin.

FIGURE 3-34 Barrier cream acts as a protective layer, preventing chemicals from being absorbed into your skin. It should be applied before starting work.

Cleaning Your Hands When cleaning your hands, use only specialized hand cleaners, which protect your skin. Your hands are porous and easily absorb liquids on contact. Never use solvents such as gasoline or kerosene to clean your hands, because they can be absorbed into the bloodstream and remove the skin's natural protective oils.

Hearing Protection

Ear protection should be worn when sound levels exceed 85 decibels, when you are working around operating machinery for any period of time, or when the equipment you are using produces loud noise. If you must raise your voice to be heard by a person who is 2 ft (0.6 m) away from you, then the sound level is about 85 decibels or more. Ear protection comes in two forms: One type covers the entire outer ear, and the other is fitted into the ear canal (**FIGURE 3-35**). Generally speaking, the in-ear style has higher noise-reduction ratings. If the noise is not excessively loud, either type of protection will work. If you are in an extremely loud

FIGURE 3-35 Ear protection comes in two forms, in-ear protection fits in and conforms to the inside of the ear. Over-the-ear protection fits over the outside of the ears.

environment, you will want to verify that the option you choose has a high enough rating. You can also use double hearing protection, by using both in-ear and over-the-ear devices.

Breathing Devices

Dust and chemicals from your workspace can be absorbed into the body when you breathe. When working in an environment where dust is present or where the task you are performing will produce dust, you should always wear some form of breathing device. There are two types of breathing devices: disposable dust masks and respirators.

Disposable Dust Masks A disposable dust mask is made from paper with a wire-reinforced edge that is held to your face with an elastic strap. It covers your mouth and nose and is disposed of at the completion of the task (**FIGURE 3-36**). This type of mask should be used only as a dust mask and should not be used if chemicals, such as paint solvents, are present in the atmosphere.

Respirator A respirator has removable cartridges that can be changed according to the type of contaminant being filtered. Always make sure the cartridge is the correct type for the contaminant in the atmosphere. For example, when chemicals are present, use the appropriate chemical filter in your respirator. The cartridges should be replaced according to the manufacturer's recommendation to ensure their effectiveness. To be completely effective, the respirator mask must make a good seal on your face (**FIGURE 3-37**).

SAFETY TIP

A dust mask or respirator will filter out only particulate contaminants. They will not protect you in an atmosphere in which there is not enough oxygen to sustain life. In these cases, a closed respiratory system with its own oxygen supply must be used.

Eye Protection

Eyes are very sensitive organs, and they need to be protected against damage and injury. There are many things in the shop environment

FIGURE 3-36 A disposable dust mask covers both the nose and mouth and is thrown away at the end of the task.

FIGURE 3-37 To be effective, the respirator mask must make a good seal on your face.

that can damage or injure eyes, such as high-velocity particles coming from a grinder or high-intensity light coming from a welder. In fact, the American National Standards Institute (ANSI) reports that 2,000 workers per day suffer on-the-job eye injuries. Always select the appropriate eye protection for the work you are undertaking. Sometimes this may mean that more than one type of protection is required. For example, when grinding, you should wear a pair of safety glasses underneath your face shield for added protection.

Safety Glasses The most common type of eye protection is a pair of safety glasses, which must be marked with “Z87” on the lens and frame. Check with your supervisor for the specific protective eyewear rating required at your job site. Safety glasses have built-in side shields to help protect your eyes from the side. Approved safety glasses should be worn whenever you are in a shop. They are designed to help protect your eyes from direct impact or damage from flying debris (**FIGURE 3-38**). The only time they should be removed is when you are using other eye protection equipment. Prescription and tinted safety glasses are also available. Tinted safety glasses are designed to be worn outside in bright sunlight conditions. Never wear them indoors or in low light conditions, because they reduce your ability to see.

FIGURE 3-38 Safety glasses are designed to protect your eyes from direct impact or damage from flying debris.

Welding Helmets Wear a **welding helmet** when using or assisting a person using an electric welder. The light from a welding arc is very bright and contains high levels of ultraviolet radiation. The lens on a welding helmet has heavily tinted glass to reduce the intensity of the light from the welding tip, allowing you to see the task you are performing more clearly (**FIGURE 3-39**). Lenses come in a variety of ratings depending on the type of welding you are doing; always make sure you are using a properly rated lens. The remainder of the helmet is made from a durable material that blocks any other light from reaching your face. Welding helmets that tint automatically when an arc is struck are also available. Their big advantage is that you do not have to lift and lower the lens by hand.

Gas Welding Goggles **Gas welding goggles** can be worn instead of a welding mask when using or assisting a person using an oxyacetylene welder (**FIGURE 3-40**). The eyepieces are available in heavily tinted versions, but they are not as tinted as

FIGURE 3-39 The lens on a welding helmet is heavily tinted to reduce the intensity of the light from the welding arc, while still allowing you to see what you are doing.

FIGURE 3-40 Gas welding goggles can be used instead of a full-face welding helmet when using or assisting someone using an oxyacetylene welder.

those used in an electric welding helmet. There is no ultraviolet radiation from an oxyacetylene flame, so the welding helmet is not required. However, the flame is bright enough to damage your eyes, so always use goggles of the correct rating.

Full-Face Shield It is necessary to use a full-face shield when using solvents and cleaners, epoxies, and resins or when working on a battery (**FIGURE 3-41**). The clear mask of the face shield allows you to see all that you are doing and will protect your entire face from chemical burns should there be any splashes or battery explosions. It is also recommended that you use a full-face shield combined with safety goggles when using a bench or angle grinder.

Safety Goggles Safety goggles provide much the same eye protection as safety glasses but with added protection against harmful chemicals that may splash up behind the lenses of glasses (**FIGURE 3-42**). Goggles also provide additional protection from foreign particles. Safety goggles must be worn when servicing air-conditioning systems or any other system that contains

FIGURE 3-41 It is necessary to use a full-face shield when using a grinder, solvents and cleaners, epoxies, and resins and when working on a battery.

FIGURE 3-42 Safety goggles offer much the same eye protection as safety glasses but with the added protection of preventing liquids and debris from entering from the sides of the lens.

pressurized gas. Goggles can sometimes fog up when in use; if this occurs, use one of the special anti-fog cleaning fluids or cloths to clean them.

► TECHNICIAN TIP

Each lab/shop activity will require at least the safe use of safety glasses, clothing, and shoes depending on its nature. Research and identify whether any additional safety devices are required for every activity you undertake.

Hair Containment

It is easy to get hair caught in rotating machinery, such as drill presses or running engines, and it can happen very quickly. If your hair gets caught in the machinery, you can be pulled into the machinery and injured or killed. Hair should always be tied back and contained within a hairnet or cap. Your shop will have policies and procedures relating to appropriate hairstyles for shop activities. Research the policy and procedures to determine appropriate hairstyles for activities. Always wear your hair according to the policy and procedures. Use hairnets, caps, or elastic bands as required for each activity.

Watches and Jewelry

When in a shop environment, watches, rings, and jewelry present several hazards. They can get caught in rotating machinery, and because they are constructed mainly from metal, they can conduct electricity. Imagine leaning over a running engine with a dangling necklace: it could get caught in the fan belt and be ripped from your neck. Not only will it get destroyed, but it could also seriously injure you. A ring or watch could inadvertently short out an electrical circuit, heat up quickly and severely burn you, or cause a spark that may make the battery explode. A ring can also get caught on moving parts, breaking the finger bone or even ripping the finger out of the hand (**FIGURE 3-43**). To be safe, always remove watches, rings,

FIGURE 3-43 Wearing rings and other jewelry while operating machinery or lifting heavy items may cause severe injury.

and other jewelry before starting work. Not only is it safer to remove these items, but also your valuables will not get damaged or lost.

High-Pressure Fluid Injection Injuries

A specific type of hazard that a MORE technician should be aware of is high-pressure fluid. As a MORE technician, you will be working on and around various hydraulic and pneumatic systems under extreme pressures. It may be difficult to believe, but high-pressure equipment such as hydraulic lines, high-pressure grease guns, and high-pressure fuel injection systems have the potential to cause serious injury and even death. The pressure in these systems can be more than 12,000 psi. A small pinhole, or crack in a high-pressure hydraulic hose or fuel injection line, can cause fluid to escape at a velocity of over 600 ft per second. This causes a great deal of force in a small area that can act like a needle or a knife, puncturing gloves or outer garments and penetrating the skin. These high-pressure fluid injection injuries usually require emergency medical treatment. When the fluid enters the body, it kills tissue and gangrene will begin to occur if it is not treated. Fluid injection injuries are often painless and very small. Pain and swelling may not occur for several hours after the initial injury. Failure to seek medical help quickly may result in the need to amputate fingers and limbs. Furthermore, there is a risk of blood poisoning and bacterial infection (**FIGURE 3-44**).

What to do if you suspect a fluid injection injury If you suspect a person has a fluid injection injury get them to a hospital immediately. In addition, take the MSDS for the fluid with you and inform the medical staff that the injury may be a high-pressure fluid injection injury. Inform the hospital staff of the type of fluid and provide them with the copy of the MSDS.

How to prevent fluid injection injuries If the system must be pressurized to find the source of a leak, stand well away from the suspected leak area and wear the appropriate PPE, such as a full-face shield, thick gloves, and overalls. Use a piece of cardboard or wood, and place it near the suspected leak area until the location of the leak is detected. Do not place any part of your body near a potential high-pressure leak.

FIGURE 3-44 High-pressure fluid injection injuries can be overlooked and might appear harmless. But they require immediate surgery and can cause great damage to tissues if left untreated.

One of the easiest and most effective ways to protect yourself from injury is by using the appropriate PPE. Ensure that before performing a work task, or operating a machine, you research what, if any, PPE is required. Also, ensure that the PPE you are using meets applicable safety standards. It can be tempting not to use the proper PPE, to make working easier or speed things up—but the consequences can be severe.

► Safe MORE Service and Repair

K03006

MORE machines must be put into a safe condition when technicians are about to perform service or repair procedures on them. When a machine problem is being diagnosed, it will need to remain in a working condition and all applicable hazards related to a live running machine must be adhered to. This includes keeping all personnel clear of the danger zone, having spotters when travelling or working in close quarters, communicating with other machine operators that are close by, and ensuring the operator is familiar with operating the machine.

Once a machine is ready for servicing or having repairs performed on it, there are steps to take to make the machine safe to work on. This ensures that all sources of potential energy (hydraulic, electrical, and potential kinetic) on the machine are neutralized and/or unable to be released in an uncontrolled manner. The following examples are common practices used to make machines safe to work on. Always refer to the machines service information to be aware of all machine-specific procedures needed to put a machine into a safe condition.

Lock Out Tag Out

There will be variations of **LOTO (Lock Out Tag Out)** procedures for different shops, employers, and jurisdictions. However, the desired outcome of any LOTO system is to prevent unwanted start-up or movement of a machine while it is being worked on. Every technician must be aware of their company's LOTO policies and adhere to them. Disregard for LOTO procedures can be cause for dismissal or other types of discipline.

Today, almost all MORE machines will have a master disconnect switch that will have a lock hasp around it. It is usually part of the main battery ground circuit, and by turning off this switch and locking it out, the machine cannot be started. Every employee that works for a company that has a LOTO policy will have a personal lock with their identification on it. The worker must use their lock to lock out the machine they are working on, and they are the only ones that can normally remove it. If there is more than one technician working on a machine, a lock out box will need to be used. The box will contain the key for the lock on the machine, and it provides several locations for multiple technicians to apply their locks. Tagging out a machine involves placing a "Do Not Operate" tag on the machine to notify anyone that the machine is locked out, when it was locked out, and why it has been locked out (**FIGURE 3-45**).

FIGURE 3-45 MORE machine that displays a “Do No Operate” tag and has wheel chocks applied.

Wheel Chocks

Wheel chocks are used in a repair shop to ensure a rubber-tired MORE machine doesn’t roll in an uncontrolled manner. It is common practice that as soon as a machine is parked in a shop, wheel chocks are placed on both sides of one wheel (Figure 3-45).

Wheel chocks are available in a range of sizes for all sizes of machines.

Implement Locks

When working on MORE machines, it may be necessary to get into pinch points. These are areas where serious injury or death can occur if mechanical locks aren’t put in place. For example, a tractor loader backhoe will have a boom cylinder lock that once installed with the boom raised will mechanically prevent it from lowering. Other common implement locks are for dump boxes on trucks and steering locks for articulated machines. These locks should always stay with the machine and are usually painted red to identify them (**FIGURE 3-46**).

FIGURE 3-46 MORE machine that is having a steering lock applied.

Depressurizing Accumulators

Many MORE machines will have one or more hydraulic accumulators. These devices are designed to store pressurized hydraulic fluid and are part of steering, brake, or hydraulic systems.

Before work is done on these systems, these accumulators must be de-energized. Always refer to the machine’s service information for the proper way to do this. For example, a brake accumulator could be bled down by pumping the brake pedal while monitoring system pressure.

De-energizing High-Voltage Electrical Systems

Some MORE machines will have high-voltage electric drive systems. There is a chance that even after the machine’s engine is shut off, high voltage could be present.

To confirm that no high voltage is present, a detailed procedure must be followed. This includes very specific PPE for the task and includes training to know how to properly perform the task.

► Wrap-Up

Safety is an investment by both you and your employer, in you. If you do not consider safety worth investing your time, knowledge, and effort into, you or others around you will pay a high price at some point. Having a safe attitude is a cheap insurance policy against injuries, and it also demonstrates your professionalism.

Ready for Review

- ▶ It is everyone’s responsibility to maintain a safe working environment.
- ▶ Anyone has the authority to stop an operation that is unsafe.
- ▶ Hazards should be identified before beginning a task or operating equipment.
- ▶ Attempt to eliminate a hazard or risk if possible; if not possible, apply risk control measures to reduce the risk of an accident or mishap.
- ▶ Effective workplace safety policies save money by reducing expensive employee injuries and equipment downtime due to accidents.
- ▶ Employees must know and abide by government and shop regulations, especially concerning safety.
- ▶ Employers are required to maintain copies of all MSDS for all hazardous substances they have on site.

- ▶ Employees should be aware of where MSDS are in their shop.
- ▶ Employees should be aware of the location of emergency equipment such as fire extinguishers, fire alarms, emergency eyewash stations, first aid kits, AEDs, and hazardous material spill kits.
- ▶ Employees must know what to do in an emergency before one occurs: There will not be enough time to learn what to do during an emergency.
- ▶ Employers are responsible for providing employees with the proper PPE in order to perform their jobs and for training them on the proper selection and use of PPE for the different tasks in the workplace.
- ▶ Employees are responsible for using the proper PPE to protect themselves and others from injury.
- ▶ *Do not* attempt to disable, remove, or cheat operator protection systems on machinery and equipment.
- ▶ Conduct a hazard assessment and read the operator or repair manual before operating or repairing any equipment you are not familiar with.
- ▶ MORE machines must be put in a safe condition prior to service or repairs being performed on them. This includes locking out the machine, using wheel chocks, and de-pressurizing accumulators.

Key Terms

Automated External Defibrillator (AED) A portable device that checks the heart rhythm and can send an electric shock to the heart to try to restore a normal rhythm. AEDs are used to treat sudden cardiac arrest (SCA).

National Institute for Automotive Service Excellence (ASE) An independent, nonprofit organization that seeks to improve the quality of automotive repair by testing and certifying automotive service professionals.

back brace A piece of PPE that protects the back by bracing, which is used when heavy or frequent lifting is involved.

barrier cream A cream that looks and feels like a moisturizing cream but has a specific formula to provide extra protection from chemicals and oils.

caution Indicates a potentially hazardous situation, which, if not avoided, may result in minor or moderate injury.

complicated fracture A fracture in which the bone has penetrated a vital organ.

danger Indicates an immediately hazardous situation, which, if not avoided, will result in death or serious injury.

danger zone Area of a machine where if a person were to have a body part during the machine cycle would incur injury.

dislocation The displacement of a joint from its normal position, which is caused by an external force stretching the ligaments beyond their elastic limit.

double-insulated Tools or appliances that are designed in such a way that no single failure can result in a dangerous voltage coming into contact with the outer casing of the device.

ear protection Protective gear worn when the sound levels exceed 85 decibels, when working around operating machinery

for any period of time, or when the equipment you are using produces loud noise; also called hearing protection.

Environmental Protection Agency (EPA) A U.S. federal government agency that deals with issues related to environmental safety.

evacuation routes A safe way of escaping danger and gathering in a safe place where everyone can be accounted for in the event of an emergency.

external bleeding The loss of blood from an external wound, where blood can be seen escaping.

fire blanket A safety device designed to extinguish incipient (starting) fires. It consists of a sheet of fire retardant material that is to be placed over a fire in order to smother it.

first aid The immediate care given to an injured or suddenly ill person.

first aid kit A kit containing items needed to apply emergency first aid, such as bandages, gauze, medical tape, and other items.

first-degree burns Burns that show reddening of the skin and damage to the outer layer of skin only.

flash point The lowest temperature at which vapors of a volatile material will ignite when given an ignition source.

gas welding goggles Protective gear designed for gas welding, which provide protection against foreign particles entering the eye and are tinted to reduce the glare of the welding flame.

hazard Anything that could hurt you or someone else.

hazard control measures Actions taken to reduce, eliminate, or lessen the possible damage from hazards.

hazardous environment A place where hazards exist.

hazardous material Any material that poses an unreasonable risk of damage or injury to persons, property, or the environment if it is not properly controlled during handling, storage, manufacture, processing, packaging, use and disposal, or transportation.

headgear Protective gear that includes items like hairnets, caps, or hard hats.

heat buildup A dangerous situation that occurs when the glove can no longer absorb or reflect heat and heat is transferred to the inside of the glove.

HEPA (high-efficiency particulate absorption) A type of particulate air filter, which is effective at filtering out fine particles and dust.

internal bleeding The loss of blood into the body cavity from a wound, where there is no obvious sign of blood.

LOTO (Lock Out Tag Out) A system that must be adhered to that ensures a machine is safe to work on. The machine's energy sources are neutralized, and the machine is prevented from starting.

Material Safety Data Sheets (MSDS) Same as safety data sheets (SDS).

MSHA (Mine Safety and Health Administration) A U.S. federal government agency created to provide safety and regulatory enforcement in mining activities.

occupational safety and health A multidisciplinary field concerned with the safety, health, and welfare of people in the workplace.

Occupational Safety and Health Administration (OSHA) A U.S. federal government agency created to provide national leadership in occupational safety and health.

operating manual A manual published by an equipment manufacturer with information on how to safely and properly operate equipment.

operator protection systems Safety systems and devices designed to protect the operator of machinery from injury.

open fracture A fracture in which the bone is protruding through the skin or there is severe bleeding.

Personal Protective Equipment (PPE) Safety equipment designed to protect the technician, such as safety boots, gloves, clothing, protective eyewear, and hearing protection.

policy A guiding principle that sets the shop direction.

procedure A list of the steps required to get the same result each time a task or activity is performed.

reactivity The rate at which a substance will undergo a chemical reaction. The higher the reactivity, the faster it will chemically react.

repair and maintenance manual A manual published by an equipment manufacturer with information on how to safely and properly maintain, repair, and troubleshoot equipment.

respirator Protective gear used to protect the wearer from inhaling harmful dusts or gases. Respirators range from single-use disposable masks to types that have replaceable cartridges. The correct types of cartridge must be used for the type of contaminant encountered.

risk Exposing a person or a valuable item to danger, harm, or loss.

risk controls Measures or actions taken to reduce and control risk.

Society of Automotive Engineers (SAE) A U.S.-based, globally active professional association and standards developing organization for engineering professionals in various industries, including automotive; mobile, off-road equipment; commercial truck; and aerospace. It sets industry standards and regulations.

safety The condition of being protected from or unlikely to cause danger, risk, or injury to yourself or others.

Safety Data Sheets (SDS) Sheets that provide information about handling, use, and storage of materials that may be hazardous; also called material safety data sheets.

second-degree burns Burns that involve blistering and damage to the outer layer of skin.

shock Inadequate tissue oxygenation resulting from serious injury or illness.

simple fracture A fracture that involves no open wound or internal or external bleeding.

spill kit A kit or container containing items needed to clean up and control liquid and hazardous material spills.

sprain An injury in which a joint is forced beyond its natural movement limit.

strain An injury caused by the overstretching of muscles and tendons.

technical manual A collection of information (paper or electronic) containing specific technical data regarding how to properly operate, maintain, repair, or troubleshoot a piece of equipment. Technical manuals may also contain technical data on how to complete a task or procedure.

technical safety bulletins Documents periodically published and distributed by an equipment manufacturer, in which they identify a safety risk or hazard and how to properly control the risk or hazard.

third-degree burns Burns that involve white or blackened areas and damage to all skin layers and underlying structures and tissues.

Threshold Limit Value (TLV) The maximum allowable concentration of a given material in the surrounding air.

toxic dust Any dust that may contain fine particles that could be harmful to humans or the environment.

warning Indicates a potentially hazardous situation, which, if not avoided, could result in death or serious injury.

welding helmet Protective gear designed for arc welding; it provides protection against foreign articles entering the eye, and the lens is tinted to reduce the glare of the welding arc.

Review Questions

- Which of these IS NOT a benefit of an effective workplace hazard prevention and control system?
 - It avoids unnecessary injuries and illnesses to personnel.
 - It increases employee morale and job satisfaction.
 - It allows employees to have a party when we reach 365 days with no lost time incidents.
 - It minimizes downtime due to equipment damage from safety mishaps.
- Personal protective equipment (PPE) includes all of the following EXCEPT:
 - Safety glasses
 - Portable welding screen
 - Welding helmet
 - Steel-toe shoes
- True or False. The most effective operator protection system is not to place your hand in the machine's danger zone.
 - True
 - False
- Effective control measures to minimize the risk of an accident includes all of the following EXCEPT:
 - Your supervisor will tell you how to minimize all risks.
 - Read the manufacturer's operator manual before using equipment.
 - Conduct a walk-around inspection to ensure the machine is safe before operating.
 - Ensure all operator protection systems are in place and operating correctly before using equipment.
 - Read your shop safety policies before beginning work at a new job.

5. True or False. Guards on machinery can be removed to speed up production if you are confident you know what you are doing.
 - a. True
 - b. False
6. How long can a diesel engine be operated indoors before an exhaust extraction hose should be attached?
 - a. The engine can be run indefinitely as long as the shop bay doors are opened.
 - b. The engine can be run for up to 30 minutes.
 - c. It depends on your shop policy.
 - d. Gasoline and diesel engine equipment should not be run indoors without an exhaust extraction device attached.
7. There are three signal words: _____, _____, and _____.
 - a. stop; warning; danger
 - b. warning; general; danger
 - c. danger; warning; caution
 - d. caution; stop; danger
8. The maximum OSHA permissible exposure limit (PEL) for carbon monoxide is parts per million (ppm) of air for an 8-hour period.
 - a. 20
 - b. 30
 - c. 40
 - d. 50
9. Typically, there should be of unobstructed space around an electrical panel.
 - a. 1'
 - b. 2'
 - c. 3'
 - d. None of the choices is correct.
10. Which of the following bulb types presents an extreme fire hazard if broken in the presence of flammable vapors or liquids?
 - a. Incandescent
 - b. LED
 - c. Fluorescent
 - d. None of the choices is correct.

ASE Technician A/Technician B Style Questions

1. Technician A says that the press brake machine must be taken out of commission because the operator protection system has been disabled. Technician B says that he has never been injured, and it has always been like that. So, you should not have a problem operating the machine. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says that reading the equipment operating manual is not needed because all warnings are clearly posted on the machine itself. Technician B says that it is always good practice to read the operating manual before using unfamiliar equipment. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says that you should read the label on the product to determine what, if any, hazards it poses. Technician B says that you should read the MSDS on the product to determine what, if any, hazards it poses. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
4. Technician A says that OSHA regulations are the most correct source of information about all safety-related processes and procedures that must be done in the shop. Technician B says that the equipment manufacturer operating and repair manuals are the most correct source of information regarding the operation of specific equipment. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says that you should read the label on the product to determine what, if any, hazards it poses. Technician B says that you should read the MSDS on the product to determine what, if any, hazards it poses. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
6. Technician A says if the diesel engine is running "clean," you do not have to attach an exhaust extraction hose to run it indoors. Technician B says that you can operate a diesel engine indoors if there is proper ventilation, like having the bay doors open. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
7. Technician A says that the best way to stop bleeding is to apply a tourniquet first. Technician B says that you should try to elevate, apply pressure, and use gauze and bandages before using a tourniquet. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says that should use a fire blanket to attempt to put out an engine fire. Technician B says that you use a

fire extinguisher to attempt to put out an engine fire. Who is correct?

- a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B
- 9.** Technician A says that you should use only a welding helmet during electric arc welding. Technician B says that you can use welding goggles for electric arc welding, as it is less restrictive and allows you to see your work material better. Who is correct?
- a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B

10. Technician A says that you should use chemical gloves when handling grease and oils. Technician B says that you can use barrier cream when handling grease and oils. Who is correct?

- a.** Technician A
- b.** Technician B
- c.** Both Technician A and Technician B
- d.** Neither Technician A nor Technician B

CHAPTER 4

Bearings, Seals, Lubricants, Gaskets, and Sealants

Knowledge Objectives

After reading this chapter, you will be able to:

- **K04001** Describe and explain the purpose, operation, and construction of seals and bearings.
- **K04002** Outline the procedures used to install seals and bearings.
- **K04003** Describe and perform the steps used to adjust bearing preload.
- **K04004** Describe and perform the steps used to replace a seal.
- **K04005** Identify and explain causes of seal and bearing failures.
- **K04006** Outline and perform the steps required to replace a gasket.
- **K04007** Identify and describe the types and applications of sealants.
- **K04008** Identify and classify commonly used fluids and lubricants.

Skills Objectives

After reading this chapter, you will be able to:

- **S04001** Select and correctly use fluids and lubricants commonly used in the industry.
- **S04002** Select and use the proper tools for replacement of bearings and seals.

Attitude Objectives

After reading this chapter, you will be able to:

- **A04001** Locate and adhere to OEM service procedures for servicing seals, bearings and gaskets.

► Introduction

A typical heavy equipment machine will have many types of bearings, seals, gaskets, sealants, and lubricants. Together, these items are some of the most critical components in any piece of heavy equipment. These items allow other components to continue to operate properly, and without them, many other critical parts would fail quickly. Despite advances in material and construction, bearings, seals, gaskets, and lubricants are a point of considerable wear and stress and require periodic maintenance and repair. A heavy-duty equipment technician will spend a significant amount of time maintaining and servicing these components. You must be familiar with their purpose, operation, construction, types, and repair procedures to ensure they are serviced properly.

The History of Bearings, Seals, Gaskets, and Lubricants

The use of bearings goes back thousands of years, predating the Industrial Revolution of the 1700s. Some of the earliest known uses of bearings were in the form of wooden rollers supporting the moving of heavy objects. There also exist engineering drawings created by Leonardo da Vinci dating back to the 1400s and 1500s showing enclosed ball bearings. In fact, some wooden bearings are still in use today for certain applications. Seals have also been in use for thousands of years in various forms. Some of the earliest types of seals and gaskets consisted of simple rope coated in tar, pitch, or animal fats (also called tallow). In fact, rope seals still exist for some applications. During the era of the steam engine, a stuffing box (also called a packing seal, gland seal, or gland packing) was used to prevent leakage of fluid between sliding or rotating parts. Since World War II, mechanical seals have replaced the packing and gland seals in shaft sealing applications.

Prior to the widespread use of petroleum lubricants in the late 1800s, most lubricants were made of plant- or animal-based materials such as tar, pitch, plant and animal oils, and animal fats. During and after World War II, when synthetic oil and lubricant production became more widespread, it became possible to create lubricants and oils for almost any application. Since then, synthetic lubricants have become more specialized, and many equipment manufacturers use lubricants that have very specific properties and specifications. Therefore, it is crucial to verify that the lubricants you are using fulfill the specific equipment manufacturer's specifications as published in

the manufacturer's service and repair manual. Failure to use the exact lubricants specified by the equipment manufacturer can result in voided warranty, equipment damage, premature wear to components, and decreased operation efficiency.

► Purpose, Operation, and Construction of Seals and Bearings

K04001, A04001

Purpose of Bearings

Bearings play an important part in keeping heavy-duty (HD) equipment and machines working. They are designed to greatly reduce friction between moving parts by keeping them separated and allowing relative motion in the desired direction. If two parts are allowed to contact each other while there is relative motion, then the increase in friction will create heat. If enough heat is created, the parts will start to weld themselves together, similar to inertia welding. Bearings are also designed to constrain movement to only the desired direction and to support a load.

Operation of Bearings

Bearings reduce friction by using rolling elements such as rollers and balls in their construction. In slow **linear** movement applications, plain bushings can be used, which consist of materials that have a low **coefficient of friction** with one another.

Bearings are also designed to carry a load. A load can be applied to a bearing in either of two basic directions: radial and axial. **Radial** loads act at right angles to the shaft (bearing's axis of rotation). **Axial (thrust)** loads act parallel to the axis of rotation (along the shaft). See **FIGURE 4-1** for a good visual representation the loads on a bearing and shaft.

The ability of a bearing to carry a load is influenced by several factors, including the type of bearing (ball, roller, or bushing type), the number of roller elements, the type of material the bearing and roller elements are composed of, and the total surface contact area of all the roller elements. For example, due to a roller bearing's larger total surface contact area of the roller elements compared to an equivalently sized ball bearing, roller bearings are used for applications with higher radial loading. Overloading in the axial or radial direction of any type of bearing can cause deformation and premature bearing failure. For

You Are the Mobile Heavy Equipment Technician

You and another heavy-duty equipment technician are preparing to replace the left-side axle shaft seal on the rear differential of a hydraulic front end loader. This requires removing the entire axle shaft from the differential to complete.

1. What types of environmental and personnel hazards may be present during this repair operation?
2. What types of general or specialty tools may be required to properly complete this repair operation?
3. What are the critical areas to inspect in order to ensure the axle shaft seal will not fail again prematurely?
4. What (if any) manufacturer technical data should you look up before beginning the repair?
5. How do you determine what type, and specification, of axle fluid to use to refill the axle once the repair is complete?

The resultant moment load (M) equation:
 $M = (\pm T) (S_t) + (\pm R) (S_r)$

FIGURE 4-1 Axial and radial loads applied to a bearing and shaft.

this reason, a heavy-duty equipment technician should pay close attention to bearing failures and determine the root cause of failure. If overloading or another external source caused a bearing to fail prematurely, the replacement bearing will also fail prematurely if the external cause of failure is not corrected.

Types and Construction of Bearings

Almost all bearings are made from metal, but some light-duty bearings could be non-metallic, such as wood or plastic. The size and type of bearing used mostly depends on the amount of load and speed during normal operation between the two parts that the bearing is separating. Next, we will explore several types of bearings, including their descriptions and applications.

Friction Bearings (Plain Bushings)

Friction Bearings, or Plain Bushings, can be used for slow, linear movement like an extendable backhoe stick; partial, slow rotation of components like bucket linkages; or very fast rotating components like engine camshafts (**FIGURE 4-2**).

A friction bearing is characterized by its lack of roller elements. It simply consists of a cylinder that surrounds a moving or rotating shaft. The bearing can be a split shell type, or a single piece construction. The bearing is designed to have a small gap between the inner bearing surface and the moving shaft to prevent metal-on-metal contact. In high-speed rotating applications, the air gap is filled with a high-pressure oil film, which the shaft rides on (**FIGURE 4-3**).

The bearing material is selected to provide a low **coefficient of friction**, good wear and fatigue strength, and an imbedded ability to resist damage to the bearing or shaft from particles. These bearings can consist of one or more types of materials sandwiched together to provide the desired characteristics. The dimensional tolerance, or gap, between the bearing inner surface and the moving shaft is critical. If the gap is too large, this will cause excessive shaft movement. In

FIGURE 4-2 A camshaft bearing is a type of friction bearing. It uses pressurized oil to provide a thin film of oil between the bearing's inner surface and camshaft, which the camshaft rides on. Notice the oil hole.

FIGURE 4-3 A camshaft bearing uses a thin film of pressurized oil to carry the load and act as a low friction bearing surface for the camshaft.

bearings that use high-pressure lubrication, this will cause a possible loss of the oil film between the bearing and the shaft and a possible loss of oil pressure at the bearing. If the gap is too small, this may result in metal-to-metal contact and excessive wear between the bearing and the shaft during expansion and contraction due to heat.

Plain Spherical Bearings

Plain spherical bearings are also a friction-type bearing in that they do not use roller elements, though there are spherical bearings that do use roller elements. This type of bearing is used in applications that require a mechanical linkage between two parts, but the angle between the parts varies or is not parallel or perpendicular to one another (**FIGURE 4-4**).

Some examples of plain spherical bearings are in tie rod ends used in steering systems (**FIGURE 4-5**). Because the angle between the steering linkage and the steering knuckle where the steering linkage attaches is not the same throughout the movement of the steering, a simple eyelet and pin cannot be used.

FIGURE 4-4 A plain spherical bearing. Notice the inner and outer rings and how the angle between the rings can vary.

FIGURE 4-5 Two plain spherical bearings used in a steering tie rod. Note the grease fittings.

FIGURE 4-6 A plain spherical bearing used in the eyelet ends of a hydraulic cylinder.

Other examples of plain spherical bearings include ball joints as well as spherical bearings placed into the eyelet ends of a hydraulic cylinder (**FIGURE 4-6**).

The plain spherical bearing consists of an inner spherical ring placed within an outer spherical ring and locked together so that the inner ring is held captive within the outer ring in

the axial direction only. The inner ring is free to rotate and change angle radially (within certain limits based on the bearing design), but cannot move axially. The outer surface of the inner ring and the inner surface of the outer ring, called the raceway, slide against each other. Plain spherical bearings are either lubricated with a grease fitting or are of a maintenance-free design. This type of bearing is normally made from hardened steel.

► TECHNICIAN TIP

"Maintenance-Free" Bearings & Joints: Do not assume just because a bearing or joint does not have a grease fitting that it is "maintenance-free" and does not require lubrication. Also, do not assume that because one bearing or joint on a piece of heavy equipment does not have a grease fitting, the entire piece of machinery is "maintenance-free" and requires no lubrication. Verify the proper lubrication points and schedule in the manufacturers service and maintenance manual or lubrication data plate.

Occasionally, plain friction bearings will be mounted on rotating shafts. They are typically installed in the bore, or housing, of a component with an **interference fit** so that the bearing remains stationary relative to the bore, or housing, it is mounted into. An interference fit, also called a **press fit** or **friction fit**, is a means of fastening two parts together so that they are in direct contact with one another and are held in place only by friction, or the tightness of the fit. The amount of friction between two surfaces is directly proportional to the force that presses them together. Because of this, a great deal of force is applied to install and uninstall interference-fit joints. However, if too much force is applied during installation and disassembly, the parts can deform and be damaged. Assembling components together using an interference fit requires using either a linear or a transverse method. In the linear method, a force is applied to the components linearly along the axis of the shaft to push the component onto the shaft using a **hydraulic press**, an **arbor press**, a **bearing driver**, or something similar. In the transverse method, either the outer part is expanded with heat or the inner part is shrunk by super cooling. The parts are then assembled and allowed to return to room temperature. As the parts return to room temperature, the gap between them closes and they touch one another. The resulting force between the parts is perpendicular, or *transverse*, and creates the friction needed to hold the parts tightly together. For bearing installation, this may require cooling the bearing or pressing the bearing into place with special tools. Bearing and component cleanliness is critical to proper installation. Bearing removal could require the use of special tools or procedures such as using a puller, press, or specific heating or cooling procedures and tools.

Rolling Type Bearings

Ball Bearings **Ball bearings** are typically used to allow independent rotation of a component and a shaft and could be used for low- or high-speed applications. They are designed to withstand mainly radial loads and limited axial loads. They are for relatively low loads because the load is concentrated on a few small spherical balls as the contact points. Ball bearings are characterized by the spherical ball rolling elements. Ball bearings

are typically constructed of an assembly with an outer **race**, inner race, spherical balls, and a bearing cage. Bearing cages are meant to keep the rolling elements of the bearing separated and evenly spaced apart. Bearing cages can be made of light plastic, soft metal or hard, machined metal depending on the bearing design. The ball bearing races act as the surface that the spherical ball elements ride, or roll, on. The bearing races are made to specific dimensions and composed of specific materials, to provide an ideal surface for the ball bearings to ride on. In some cases, the ball bearing does not have its own race, but instead, it rides directly on the shaft or inside of a hole. In these cases, the shaft or hole surface that the bearing rides on is specifically machined to act as the race for the ball bearing. Ball bearing races will usually be an interference fit for either the outer diameter of the outer race or the inner diameter of the inner race. This means that removal or installation will require a gentle heating or cooling process or a special tool. Lower-speed ball bearings could be lubricated by grease, while medium- to high-speed usage bearings will be lubricated with oil. Ball bearing assemblies could also incorporate seals to keep contamination out and lubrication in. See **FIGURE 4-7** for an exploded view of a typical ball bearing assembly.

Roller Bearings **Roller bearings** are characterized by their cylindrical roller elements. They are used in applications where a shaft exerts high radial loads with minimal axial loads (10% of axial load). Like ball bearings, roller bearings will have an inner race, outer race, cylindrical roller elements, and bearing or roller cage. Roller bearings could come preassembled or have a separate outer race. Roller bearings can be used in partial rotation and full rotation and in low- to high-speed applications. Removing a roller bearing could require special puller tools or heating tools and procedures. Roller bearing installation could require gentle heating or cooling and/or special tools. Care must be taken to push or pull on the press-fit races only when installing. Depending on their application and speed, roller bearings could be lubricated by grease or oil.

Because they are designed to carry heavy loads, roller bearings are found throughout heavy-duty equipment applications. Some examples are in wheel bearings, axle bearings, and throughout transmissions and gearboxes. There are four main

types of roller bearings: spherical, cylindrical, tapered roller, and needle bearings.

Spherical roller bearings are characterized by their barrel-shaped rollers. The rollers are narrow at the ends, and they bulge in the middle like a wooden barrel. They will handle some axial load and can tolerate slight misalignment of the two separated components. See **FIGURE 4-8** for a picture of a spherical roller bearing.

Cylindrical roller bearings are characterized by their cylinder-shaped roller elements. The axis of the rollers is parallel to the shaft. They are designed to carry heavy radial loads, and not axial loads. Any misalignment of the inner and outer bearing races will lead to excessive bearing wear and premature failure. This bearing type is the earliest and simplest type of bearing. A roller bearing can be as simple as wooden rollers placed under a heavy object. A typical application for a cylindrical roller bearing is to support the planet pinion gears in a planetary gear assembly used in final drives and power shift transmissions. See **FIGURE 4-9** for a picture of a typical cylindrical roller bearing.

Tapered roller bearings are characterized by the conical (cone-shaped) rollers (**FIGURE 4-10A**) that are arranged in at a *tapered* angle to the shaft so that the rollers form a cone shape around the shaft (**FIGURE 4-10B**).

FIGURE 4-8 A typical spherical roller bearing. Note the barrel-shaped rolling elements.

FIGURE 4-7 An exploded view of ball a bearing assembly.

FIGURE 4-9 A typical cylindrical roller bearing. Note the cylinder-shaped rolling elements.

FIGURE 4-10 **A.** Notice the cone shape of the rollers in a tapered roller bearing. **B.** Notice the cone-shaped, or tapered arrangement, of all the roller elements.

FIGURE 4-11 A large pair of tapered roller bearings used in the planetary gear set of a gearbox.

Because of their shape, tapered roller bearings can manage both axial (thrust) and radial loads. Typical applications for tapered roller bearings include wheel bearings, differential pinion gear shaft bearings and crown (ring) gear bearings, gear boxes, and many others. See **FIGURE 4-11** for a picture of a pair of medium-sized tapered roller bearings used in the planetary

gear set of a gearbox. Did you know that bearings in large industrial applications, such as power generation facilities, can be taller than a person and weigh tens of thousands of pounds?

Tapered roller bearings can be preloaded, which ensures the rollers are in full contact with the races all the way around the bearing. Tapered roller bearings will come as two separate pieces, commonly called a cup and cone. The cup is the tapered outer race, and the cone is an assembly of the tapered inner race with the rollers and a bearing cage.

Removing tapered roller bearings requires procedures similar to roller and ball bearing removals; however, bearing installation will require an adjustment procedure.

A common use for tapered roller bearings is using two bearings together to minimize the in-and-out axial movement of a shaft. A single tapered roller bearing will prevent axial movement in a single direction. However, if two tapered roller bearings are facing in opposite directions, they will restrict axial movement of a shaft in both directions. In this case, the combination of two tapered roller bearings and a preload force applied to the bearings will keep shaft axial movement to a minimum. This is a common arrangement of tapered roller bearings in differential pinion shaft bearings. The pinion shaft nut is used to apply the preload needed for the bearings. See **FIGURE 4-12** and **FIGURE 4-13** for how preload adjustments affect pinion shaft bearing applications.

Tapered roller bearing **preload** adjustment could involve adding or removing shims and/or a fastener torquing procedure. The goal of this procedure is to ensure that every roller is supporting an equal part of the load and that the amount of axial movement in the shaft is minimized. To confirm this, a specific rolling resistance must be created that equates to proper bearing preload. It is important throughout the bearing adjustment procedure to lubricate the rollers and to rotate the component to allow proper bearing seating to get an accurate reading. Preload measurement is usually accomplished by using a weight scale or torque wrench to measure the pounds or kilograms of

FIGURE 4-12 A differential pinion gear cutaway illustration showing the components.

FIGURE 4-13 A cutaway illustration showing the axial (F_a) and radial (F_r) forces acting on the pinion shaft and roller bearings. The force F_a on the left side of the illustration is exerted by tightening the pinion shaft preload nut.

force required to rotate the supported component. The equipment manufacturer will publish specifications and procedures for preload adjustment.

Needle bearings are characterized by their thin (small diameter), long, and numerous roller elements. Needle bearings can be found in universal joint caps and the pilot bearing located on the input shaft of a manual transmission.

► TECHNICIAN TIP

Don't lose your bearings! Ball bearings, roller bearings, and especially needle bearings can have very small roller elements that are easily lost. Take care during removal and installation not to lose your rolling elements, and keep each bearing separate so that rolling elements from different bearings don't get mixed together.

Purpose of Seals

Seals play an important part in keeping heavy-duty equipment and machines working. A typical heavy equipment machine will use many different types of seals. Seals are necessary to keep fluids inside compartments, separated from another fluid, to seal pressurized or unpressurized air, or to keep dirt and environmental contaminants out of compartments. There are many different types and styles of seals, and they are made of many different types of materials.

A very common repair is to fix a fluid leak because of a failed seal, so it's important to understand the different types of seals and what they are made of. **FIGURE 4-14** shows a picture of a seal that's leaking fluid.

Operation of Seals

Seals simply act as a barrier to keep unwanted elements out of an area and keep the desired materials in. Seals can be grouped into two main categories: **static** and **dynamic**. Static seals work between two stationary components, such as a cylinder head and an engine block. Dynamic seals work between two components that move in relation to each other, such as a transmission input shaft and the transmission housing. It is obvious that a seal may be needed

FIGURE 4-14 A leaking seal.

between two moving parts, because the parts must have a small gap between one another to move freely. However, someone may ask why two stationary parts cannot just be bolted directly together without the need for a seal. It may be possible to have two or more components made of the same material and having similar enough shapes to be bolted together and form a seal. In heavy-duty equipment applications, different materials and shapes are often used to manufacture components. Different materials have different rates of expansion (and to a certain degree different shapes) and contraction with changes in temperature. When two different materials are mated together, they may form a good seal at **ambient temperature**. However, when the temperature changes, they will expand and contract at different rates and will create a gap and *break the seal* at some point. Because of this, a suitable seal is used that will create a seal between the two components throughout the expected operating temperature range of the equipment.

► TECHNICIAN TIP

Be careful with that new seal! One of the most common causes of premature seal failure is damage caused to the seal during installation. Be very careful with new seals, as they are damaged easily. It is much easier to replace a new seal that became damaged as soon as the damage is detected. Once parts and components are reassembled and a leak is found upon repair verification, it becomes much more expensive and time-consuming to replace a new seal that was damaged.

Types and the Construction of Seals

There are far too many different types of seals to describe every one of them in this textbook. We will briefly review a few of the more common types of seals.

Static type seals can be broken down into different types of seals:

- O-rings
- D-rings
- X-rings
- backup rings
- flat rings.

Dynamic seals can be broken down into different types of seals:

- metal-to-metal piston ring-type seals
- taper faced metal-to-metal seals
- lip-type seals
- lip-type metal-supported seals
- spring-loaded lip-type metal-supported seals.

O-ring, D-ring, and Square-Ring Seals

These are flexible seals made from an elastomeric compound made of a base polymer that is mainly a natural or synthetic rubber. They will usually stay circular in shape in use but can sometimes fit into an odd-shaped groove or over a non-circular-shaped component. Their cross-section shape determines whether they are called an O-ring, D-ring, X-ring, or square-ring (**FIGURE 4-15**).

For the remainder of this section, all these seals will be called O-rings since they are the most common.

They are sized by their overall inside and outside diameter and cross-sectional diameter. Some different types of O-ring material are silicone, Buna-N, Viton, neoprene, and nitrile. The

type of material a seal is constructed of is based on the type of fluid or gas it will be exposed to and the normal operating temperature of the fluid or gas. This means the seal material must be compatible with the substance it is in contact with and must be able to withstand the temperatures it will be subjected to. If an O-ring is used for some non-compatible fluid or gas or out of its temperature range, it can't be expected to seal properly. If an O-ring is overheated, it will become hard, crack, and allow fluid leak. Excessive heat is the leading cause of O-ring failure.

If an O-ring is used to seal two components, it will fit into a machined groove (also called a **gland**) on one component and should get compressed by about one-third of its diameter when the second component is fastened to the first to provide a positive seal (**FIGURE 4-16**).

O-ring seals that are used with fluid fittings can be used to fit over top of the fitting and seal against a beveled shoulder in a component when the fitting is threaded into it. O-rings could also seal the fitting on its face when they fit into a groove in the fitting.

Some O-ring-type seals that are used around the circumference of a shaft or cylinder rod will require a second ring, called a backup ring.

FIGURE 4-15 **A.** A variety of O-ring type seals. **B.** A cross-sectional view of a D-ring. **C.** A cross-sectional view of a square-ring. **D.** A cross-sectional view of an X-ring.

FIGURE 4-16 A cross-sectional view of static type O-ring seal before, during, and after compression with the mating surface. Notice how the compression at the top of the O-ring from the mating surface will cause the O-ring to fill the groove area.

This will be a harder, nylon material that is placed directly beside the O-ring to provide support for it in the O-ring groove around the outside circumference of a component.

Any time components are removed for repair or service, it is common practice to replace all O-ring-type seals. This is a cheap way to ensure there won't be any seal-related leaks. The groove that the O-rings fit into must be clean and free of corrosion, to ensure a proper and long-lasting seal.

► TECHNICIAN TIP

When replacing or reassembling components with seals and gaskets, always consult the equipment manufacturer's repair and service manual to determine which seals and gaskets require replacement once removed. Many seals and gaskets are "one-time-use" items and require replacement once disassembled or removed.

O-ring-type seals can be custom-made from bulk lengths. O-ring making kits will come with measuring and cutting tools and special adhesives to join the two ends of the O-ring.

Lip-Type Seals

Lip-type seals are designed to have one or more sharp elastomeric sealing surfaces creating a seal between the seal lip and the mating circumferential surface of a component or shaft. **Radial shaft seals** are a common type of lip seal. Some lip-type seals will rotate on a stationary shaft, whereas others will be stationary, with the shaft rotating inside the seal. Lip-type seals are usually dynamic seals, meaning that they will seal between two moving components or one stationary and one moving component. These seals can be made from different types of material, such as hard urethane, flexible rubber, or a combination of either one plus a steel backing support. Lip-type seals could have oil pressure acting on the lip to help apply more force to the lip and thereby create a more effective seal. See **FIGURE 4-17** for an assortment of lip-type seals.

Some lip-type seals will use spring pressure behind the lip to assist with creating a tighter seal. You should always check this type of seal after installation to make sure the spring is still in place (**FIGURE 4-18**).

Metal-supported lip-type seals will usually be installed with an interference fit into a recess in the component. The metal backing or support for this type of seal will usually have a soft vinyl-like coating on it that will fill any inconsistencies between the metal backing and the component it is installed into.

FIGURE 4-17 **A.** A variety of lip-type seals. **B.** Cross sections of lip-type seals.

FIGURE 4-18 A radial shaft seal is a type of lip seal. Note the different seal parts labeled: **A.** Rotating shaft. **B.** Housing. **C.** Inside compartment (fluid filled). **D.** Housing face. **1.** Metal insert. **2.** Primary sealing lip. **3.** Spring. **4.** Dust seal lip.

Some lip-type seals will have their lips ride on a **wear sleeve**. The wear sleeve is a thin piece of hardened steel designed to wear down over time and should be replaced when the seal is replaced. This prevents the rotating motion from wearing down the actual components. Engine crankshafts will commonly use wear sleeves. Some lip-type seals and wear sleeves come as an assembly and must not be separated. They will require a special

installation tool, and they are used mainly for rear crankshaft seals on engines.

Metal-to-Metal Face Seals

These are sometimes called duo-cone seals, and they feature two hard, special alloy metal rings that are precisely hardened and lap fitted. The hard smooth surfaces run against each other and create a seal on their faces. The fluid that the seal contains will provide some lubrication and cooling for the seal. They will have a large elastomeric O-ring seal behind them. The O-rings will keep pressure on the metal seals after component assembly, as well as complete a seal between the outer circumference of the metal seal and the component they are mounted in. One metal seal is stationary while the other rotates against it. This type of seal is most commonly used for wheel seals and/or final drive seals. Duo-cone seals are very effective at keeping oil in and dirt out.

Duo-cone seals can be reused, provided they don't exceed recommended wear specifications and don't show other signs of failure like pitting or cracks. Wear on duo-cone seals is measured by seeing how wide the contact pattern is between the two metal parts.

Piston Ring-Type Seals

This style of seal is typically found in turbochargers and used to seal the turbo shaft. They are also found in torque converters and transmissions. They are a simple, hardened metal ring that creates a dynamic seal between two rotating parts and are very similar to piston rings. Care must be taken when installing this type of seal to not overstretch them or scratch them.

► Bearing and Seal Servicing

K04002, S04002

The following paragraphs will detail some of the methods and procedures used when replacing, removing, installing, and servicing seals and bearings.

Replacing Bearings

When parts that contain bearings are disassembled, the bearings can be reused and do not normally require replacement so long as they are still performing their function satisfactorily, pass a visual inspection, and feel smooth when rotated by hand. Do not unpack new bearings until you are ready to install them. The packaging protects the bearings. New bearings should always be lubricated with the oil they will normally run in after they are installed. Ideally, you should wear latex gloves when handling new bearings because the moisture from your hands will start corroding the bearing. When reconditioning components with bearings, the bearings should be thoroughly cleaned with a water-free cleaning solvent like Varsol and inspected. Look for imperfections such as pitting, scoring, brinelling, corrosion, chipping, smearing, discoloration, and flaking of the surface. *Do not* blow-dry bearings with full shop air pressure, because this may over-speed the roller elements and cause damage.

When inspecting bearings, follow the procedures in **SKILL DRILL 4-1**.

Bearing Removal

The method for bearing and race removal depends on the method of installation. If the bearing is not an interference fit, then removal can be as simple as removing the fasteners and components, followed by the bearing and race. However, if the bearing and/or race was installed using an **interference fit**, then special tools and procedures are required for removal. The bearing race that is secured using an interference fit is called the **press-fit** race. The bearing race that is not secured using an interference fit is called the **slip-fit** race. Bearings may have one or both races that are press fit. Numerous tools and procedures are used to ensure safe and reliable bearing removal while minimizing the chance of damage to parts during removal. Damage to bearings, races, shafts, and housings can occur when the improper tools or methods are used. Some examples of incorrect tools and methods that may cause

SKILL DRILL 4-1 Inspecting Bearings

1. There are several ways to inspect bearings for serviceability and determine if a replacement is required:

- conducting a visual inspection of the bearings and races for signs of bearing failure (Looking)
- listening to the bearings and/or components move before or after disassembly for signs of bearing failure (Listening)
- feeling and/or measuring for excessive end play in the bearing before disassembly. Also, check for excessive play and looseness after disassembly between the bearing and race and the roller elements (feeling/measuring for end play).

2. Determine whether there is there a specific customer complaint or symptom that may be caused by a bearing failure—for example, excessive noise from the front wheel that gets louder on one side during a turn.

3. Listen for problems in the bearing before disassembly, if possible. Turn the shaft, or moving portion, and listen for any excessive noise from the bearing area, such as grinding, crunching, or scraping. Try to isolate any unusual noises as much as possible before determining whether the bearing requires replacement solely based on excessive noise when turning the bearing.

SKILL DRILL 4-1 Inspecting Bearings (Continued)

4. Feel for excessive end play, or looseness, in the bearing before disassembly, if possible. Grasp the shaft, or moving portion, by hand and move it vertically and horizontally. You can also check for excessive axial movement in the shaft by pushing and pulling the shaft, or moving portion, in and out. If needed, use a **dial indicator** to measure the specific amount of end play in the bearing. In general, any perceptible movement may be an indication of excessive looseness in the bearing. However, many equipment manufacturers publish specifications for looseness, or end play, allowable in the bearing. Refer to the equipment manufacturer's repair and service manual to determine whether there is a specification listing the allowable end play before recommending the replacement of a bearing. *Note:* You must measure end play with the bearing installed. End play cannot be measured once the bearing is removed.

If any of these conditions is detected, try to eliminate other causes by isolating the specific bearing, race, and shaft in question from other rotating parts and assemblies as much as possible. Then inspect the bearing and race visually for damage and replace as needed.

7. Note that bearings and races must be replaced as a set, do not replace one without also replacing the other.

5. Feel for roughness when rotating the bearing. Bearings should turn smoothly and not have any roughness, heavy resistance, or jerking motion when turning.

If any of these conditions is detected, try to eliminate other causes by isolating the specific bearing, race, and shaft in question from other rotating parts and assemblies as much as possible. Then inspect the bearing and race visually for damage, and replace as needed.

6. Perform a visual inspection of a bearing and race to determine if there is a bearing or race failure causing a specific problem. Always clean the bearing before inspecting or reinstalling. When inspecting, the critical areas are the bearing rolling elements and the bearing races or **raceway**, so look for these specific indicators of a bearing or race failure, and replace if needed:

- pitting
- rust or corrosion
- scoring
- foreign debris damage
- nicks
- deformation to rollers, bearing cage, or race
- spalling
- damaged or broken cage or separators
- indicators of bearing overheating—brownish-blue or bluish-black coloring
- damage to integral seals
- imperfections seen or felt that require bearing and race replacement.

damage include using hammers and drift pins, unevenly applying force, and incorrect or misaligned mounting or gripping locations.

► TECHNICIAN TIP

Due to the large amount of force required to remove and install interference-fit bearings, care should be taken. The bearings, races, shafts, and housing can be damaged if too much force or improper tools or methods are used to remove or install bearings and races. When removing or installing bearings or races, if it is requiring too much force without any movement, stop and try a different method. It is much better to stop and try a different method than to permanently damage an expensive shaft or housing.

Bearing removal could include using a puller, hydraulic or arbor press, internal bearing puller (a slide hammer type), heating or cooling, or other manufacturer-recommended tools.

Methods and Tools Not Recommended for Bearing Removal

Heavy-duty equipment technicians should always follow the specific equipment manufacturer's repair and service manual for the proper tools and procedures for bearing and race removal. Failure to follow the equipment manufacturer's service and repair manual may result in damage to bearings, races, seals, shafts, housings, and other parts. Furthermore, damages

caused by not following the manufacturer's repair procedures is not covered by the manufacturer's warranty and may result in a declined warranty claim and a significant charge to the shop. There are several methods and tools that are frequently used to remove bearings and races, but they are not recommended:

- using a hammer and/or punch
- cutting the bearing with cutting equipment or a welding torch
- welding on the bearing and allowing it to cool to shrink it
- flame/torch heating.

Using a hammer and/or punch to remove bearings creates a large shock to the bearing, race, shaft, and housing, which may cause damage. Additionally, it applies an uneven amount of force in a concentrated area, which is not recommended. Cutting the bearing or race with cutting equipment or a welding torch is not recommended because doing so would have a high probability of damaging the shaft or housing. Welding on the bearing produces a great amount of heat in a small area and may damage the heat temper of other components. Flame heating also produces a great amount of heat. This will result in decreased life and weakness of shafts and housings. If heating or cooling of the bearing is required by the manufacturer, there are special tools designed to heat and cool bearings that should be used. Once again, always follow the equipment manufacturer's service and repair manual for specific bearing removal procedures.

Bearing Removal Tools

Bearing removal tools are defined by their type and maximum pulling force. The following special tools are used for bearing removal (**FIGURE 4-19**):

- hydraulic press
- arbor press
- mechanical two-jaw bearing puller
- mechanical three-jaw bearing puller
- hydraulic puller
- bearing separator or pulling plates.

Selecting the appropriate bearing removal tool depends on how well the part can be gripped and where (outside race, inside race, housing), how much reach and spread are needed, whether the component can be removed and moved to a press, and how much force is required for removal.

Hydraulic/Arbor Press A **hydraulic press** or an **arbor press** is an excellent tool for bearing and race removal and installation. It is safe when used properly, can apply a great deal of force in a controlled manner, and minimizes the chance of damaging components. Furthermore, many accessories exist for presses to assist with bearing and race installation and removal. A press can be set up to support the bearing or race while the press forces the shaft out of the bearing or to support the shaft while the bearing is forced off. Always refer to the equipment

FIGURE 4-19 Special tools used for bearing removal: **A.** Two-jaw-type bearing puller. **B.** Three jaw bearing puller. **C.** Bearing separator/pulling plates. **D.** Hydraulic press. **E.** Arbor press. **F.** Hydraulic puller.

manufacturer's repair procedure in the maintenance and repair manual for specific steps and tools required for bearing and/or race removal. While the specific setup of the press will depend on the job, these basic principles can be applied:

1. Ensure the press is in good working order.
2. Clean all mounting and contact surfaces of the press, support blocks, rings, adaptors, and bearing and race components.
3. Support the bearing or race so that the forces do not go through the rolling elements and so that you achieve the maximum contact area with the bearing or race to evenly distribute the forces (**FIGURE 4-20**).
4. Ensure the mounting and supports are steady and will not slip.
5. Ensure the axis of the bearing/race/shaft will align with the axis of the ram from the press (**FIGURE 4-21**).
6. Slowly press the ram down, to take up all the slack and ensure the parts remain aligned.
7. Apply gradual force using the ram until the parts are free and separated.
8. *Note:* If the parts begin to deform, or it is requiring an excessive amount of force, *stop* and try a different method.

SAFETY TIP

When using a hydraulic or arbor press, use proper PPE such as safety glasses. If a part shatters, it can send sharp metal debris into your eyes if not protected. Avoid placing your hands or fingers near pinch points and do not grasp or hold parts to keep them aligned while applying pressure with the ram.

Bearing Pullers Bearing pullers are used when it is not possible or it is very difficult to remove the components and bring them to a press for removal. Jaw-type bearing pullers

typically grip the bearing from the outside of the bearing. They can also be designed with reversible jaws to grip the bearing from the inside hole. Follow the equipment manufacturer's instructions as well as the bearing removal tool manufacturer's instructions when using pullers and other tools. When using bearing pullers, follow these basic principles in addition to the tool manufacturer's instructions:

- Ensure the jaws are fully engaged with the bearing press-fit race. If needed, use **adaptor plates**, also called **pulling plates**, to better grip the bearing and/or apply the force to the press-fit race. *Note:* Gripping the bearing by the slip-fit race when removing will cause all the force to go through the rolling elements and may result in damage to the bearing rollers and/or race.
- Ensure that the jaws will not slip and that they are aligned properly.
- Ensure the center forcing screw is properly aligned with the shaft. As the forcing screw is tightened, it must pull the bearing parallel to the shaft and not at an angle.
- Ensure that the bearing will not drop or fall once removed. If needed, use protection blankets or similar.

Internal Bearing Pullers The **slide hammer-type**, also called a **Blind hole bearing puller**, is a tool used when the outer bearing race is press fit into a housing (**FIGURE 4-22**).

As you can see from the image, it is not possible to grip the outside of the bearing, as it is press fit into the housing. Furthermore, the center shaft must be removed to use this tool. Follow these general steps when using this tool:

1. The tool is placed into the inner bearing hole.
2. The jaws are expanded so that they grip the bearing from the inside.

FIGURE 4-20 During bearing and race removal and installation, improper distribution of forces can result in bearing and race damage. Use appropriately sized blocks and rings for support to ensure the forces do not damage the bearing and race: **A.** Incorrect distribution of forces. **B.** Correct distribution of forces.

FIGURE 4-21 Ensure that the bearing/race has proper support and that the axis of the ram aligns with the axis of the bearing, race, or shaft.

FIGURE 4-22 A bearing race pressed into the housing.

FIGURE 4-23 Slide hammer-type internal bearing puller. The puller is inserted into the bearing hole and expanded; then the bearing is removed.

3. The shaft is tightened. See **FIGURE 4-23** for a typical slide hammer internal bearing puller set.
4. The operator then uses a slide hammer action back and forth to force the bearing loose.
5. *Note:* This tool type applies a large amount of force in a quick shocking motion to the bearing, so attempt to use the minimum amount of force needed to loosen the bearing in order to prevent bearing damage.

Internal Jaw-Type Bearing Puller This tool has the jaws reversed from the outside jaw-type bearing puller, so that it grips from the inside of a hole. This type of puller has two or more jaws. The more jaws, the more evenly pulling forces are distributed and the better the puller assembly is kept in alignment. This method is usually preferred to the slide hammer type, as it applies force gradually and not in a shocking motion. The drawback to this type is that it may not be possible to use with smaller hole diameters (**FIGURE 4-24**).

Blind Housing Bearing Puller This tool is used where it is impossible to use traditional bearing pullers. This puller would be used in applications where the outer bearing race is press fit into the housing and the inner bearing race is press fit onto the shaft. In this circumstance, neither the outer nor the inner portion of the bearing can be gripped. This tool is used only as a last resort because it destroys the bearing and can create metal shavings during the attachment process that can fall inside the housing. The following are the steps to follow to attach and use this puller:

1. A drill bit is used to drill through the bearing cage in the raceway between two ball bearings. Depending on the tool, drill the bearing cage at two points, 180 degrees opposite of one another. *Note:* Extreme care must be taken to prevent any metal shavings from falling into the housing.
2. The bearing cage is then pulled apart enough to fit the puller ends into the bearing raceway.

FIGURE 4-24 Internal jaw-type bearing puller tool.

FIGURE 4-25 Use bearing separator plates (also called pulling plates) to ensure the pulling forces are applied only to the inner press-fit bearing race.

3. The puller ends are inserted into the bearing raceway, then rotated to engage the raceway.
4. The puller is then assembled and the forcing screw is positioned to center on the shaft (or housing is some tools).
5. The operator tightens the forcing screw to take up all the slack and ensures the tool is properly aligned.
6. The forcing screw is tightened gradually to remove the bearing from the housing and the shaft.
7. The old bearing is discarded and replaced.

Bearing Separator Plates/Pulling Plates Bearing separator plates, or pulling plates, **FIGURE 4-25** are accessories typically used with bearing pullers. They are composed of a two- or three-piece metal design that is disassembled and placed around the shaft behind the bearing to be pulled. They are then reassembled and tightened. The outside of the plates has a specific area for a puller to attach firmly to. The center of the plates has a raised area that then contacts and surrounds the inner press-fit bearing race around the shaft. The plates allow for the pulling forces to be applied only to the press-fit

inner bearing race. This prevents the pulling forces from going through the rolling elements and damaging the bearing, as would be the case if only the outer slip-fit bearing race were gripped. Refer to the tool manufacturer's specific instructions for how to mount and use the plates (Figure 4-25).

► TECHNICIAN TIP

Bearing removal tools: When possible, grip the bearing at the press-fit portion of the bearing race when removing. This will prevent pulling forces from going through the bearing rolling elements and damaging the rollers or raceway. Pulling plates are an excellent way to ensure that the puller jaws have a good grip and that the pulling forces are placed on the press-fit inner race. If this is not possible, use the minimum amount of force to remove the bearing and thoroughly inspect after its removal for roller or raceway damage or deformation.

Bearing Cleaning

When you recondition components with bearings, the bearings should be thoroughly cleaned with a water-free cleaning solvent like Varsol and inspected (FIGURE 4-26). *Do not* blow-dry bearings with full shop air pressure, because this may over-speed the roller elements and cause damage. Follow these general steps to clean bearings:

1. Soak the bearings in a clean solvent bath filled with a recommended solvent for bearing cleaning. Soak overnight if possible. Keep the bearing off the bottom of the solvent bath, where dirt and debris accumulate.
2. After the bearing has been allowed to soak and loosen any dirt, debris, and old grease, rinse it in a bath of clean solvent.
3. Inspect to ensure all the dirt, debris, and old grease has been removed and the bearing is clean.
4. Allow the bearing to dry completely.
5. After drying, perform a thorough visual inspection. Rotate the bearing and rolling elements to verify proper operation.
6. Coat (or “pack”) the bearing with the same type of lubricant that it will be running in when installed in the equipment.

FIGURE 4-26 Thoroughly clean bearings with a suitable solvent, then dry it and inspect it for damage before reusing it.

Ensure the entire bearing, rollers, and raceway are completely coated in lubricant. Consult the equipment manufacturer's maintenance and repair manual for the specific lubricant type. *Note:* Do not coat the bearing in any lubricant or grease other than what it will be operating in. Coating the bearing in a different grease or lubricant may result in contamination due to incompatible lubricant types from that which the bearing will be running in when installed in the equipment.

7. If the bearing will not be immediately installed in the equipment, wrap the bearing in waterproof paper and store in a paper box or another container.
8. *Note:* A bearing with a seal, or shield, on only one side should be cleaned and inspected just like an open bearing. A bearing with a seal, or shield, on both sides should not be washed or submerged in solvent. Simply wipe the outside clean.

It is common to use a **mechanical bearing packer** to coat the bearing and to force heavy grease throughout the bearing rollers and raceway (FIGURE 4-27).

Mechanical bearing packers are easy to use; they apply lubricant more uniformly; and they are cleaner than packing with your hands.

Bearing Installation

Proper bearing installation is one of the most critical areas to ensure a long life for a bearing. Improperly installed bearings are one of the leading causes of premature bearing failure. If the bearing is not properly installed by using the correct methods and tools, the improper installation will lead to premature bearing failure. Follow the specific equipment manufacturer's instructions for installing a bearing on a piece of equipment. There are two basic methods for installing bearings that have one or more press-fit races, and the specialized tools involved depend on these methods:

- cold mounting
- hot mounting.

FIGURE 4-27 A mechanical bearing packer is very good at ensuring the bearing, rollers, and raceway are properly coated with lubricant before installation. They are also less messy, and faster than packing by hand.

Cold Mounting

Most bearings are installed using the cold-mounting method. In this method, the bearing is left at ambient temperature, and force is used to push the bearing onto the shaft or into the housing. This achieves a linear interference fit. As with bearing removal, great care must be taken to prevent damage to the bearing, races, shaft, and housing. There are two critical aspects of cold-mounting bearings.

1. Ensure the bearing is aligned properly. A bearing that is pressed on crooked, or that is misaligned, will fail prematurely and cause stress to other components. Hydraulic and arbor presses are great tools to ensure proper alignment during bearing installation.
2. Ensure the forces used to push the bearing on are concentrated on the press-fit bearing race only. Applying force to the slip-fit race will cause the pushing forces to go through the rolling elements and may damage the bearing rollers and raceway (FIGURE 4-28).

There are several types of bearing installation tools used in cold mounting. The following are the most commonly used tools:

- **bearing driver** (FIGURE 4-29)
- **hydraulic press** (FIGURE 4-30)
- **arbor press** (FIGURE 4-31).

The bearing driver kits consist of solid or hollow rings of multiple diameters, along with a cylindrical tube. One end of the tube fits into the driving rings, and the other end of the tube will be hit with a dead-blow hammer. It is important to select the driving ring with a diameter that will allow the forces to contact the press-fit race or both the press-fit and slip-fit races simultaneously. If a driving ring is selected and it contacts only the slip-fit race, damage to the bearing rollers and raceway may occur. It is also critical when mounting a bearing to ensure that the bearing and installation tool are perfectly square and that no misalignment occurs (FIGURE 4-32). Most bearing drivers can also be used as seal drivers.

FIGURE 4-28 **A.** The incorrect distribution of forces and support for a bearing install and **B.** the correct distribution of forces and support for a bearing install.

FIGURE 4-29 Bearing driver kits come with multiple diameter driving rings. Use the appropriate ring size so that all the driving forces are applied to the press-fit race or both the press-fit and slip-fit race simultaneously.

FIGURE 4-30 Just as with bearing removal, a hydraulic press is an excellent tool for bearing installation.

FIGURE 4-31 As with bearing removal, an arbor press is an excellent tool for bearing installation.

FIGURE 4-32 A bearing driver is used to install a press-fit bearing onto a shaft or into a housing. Ensure that the driving ring/adaptor is in contact with the press-fit race or both the press-fit and slip-fit race simultaneously to prevent bearing damage.

Tapered Shaft Bearing Installation

Bearings which are mounted onto a tapered shaft achieve their interference fit by being driven up the shaft. As the bearing is driven further up the shaft, the shaft diameter increases, and so the bearing fits more tightly, and more tightly onto the shaft. Care must be taken to avoid driving the bearing too far up the shaft. Driving the bearing too far up the shaft will remove all the internal clearance inside the bearing, between the rolling elements and the race. This will cause the bearing not to rotate freely, which will result in premature bearing failure and excess heat and friction (**FIGURE 4-33**).

Tapered Roller Bearing Installation

The installation of tapered roller bearings requires an adjustment called a **preload** adjustment. Tapered roller bearing preload adjustment could involve adding or removing shims and/or a fastener torquing procedure. The goal of this procedure is to ensure every roller is supporting an equal part of the load. To confirm this, a specific rolling resistance must be created that

FIGURE 4-33 Bearings installed onto a tapered shaft must not be driven too far up the shaft. This removes all the internal clearance and will result in premature bearing failure.

equates to proper bearing preload. It is important throughout the bearing adjustment procedure to lubricate the rollers and to rotate the component to allow proper bearing seating in order to get an accurate reading. Preload measurement is usually accomplished by using a fish scale to measure the pounds or kilograms of force required to rotate the supported component. The force is then multiplied by the distance from the center of the component to the attachment point of the scale. As with all bearing installations, consult the specific equipment manufacturer's repair and service manual for instructions.

Super Cooling

Some repair procedures require parts to be cooled. Many bearing installations will be easier if the bearing or part that it is installed on is cooled. The bearing, or shaft, can be cooled to shrink it. When the bearing, or shaft, heats back up to ambient temperature, it will expand and achieve a transverse interference fit. This could be as simple as using a food freezer, or it could be more complicated and hazardous, such as when using dry ice or liquid nitrogen, to super cool parts. Special caution needs to be taken and PPE needs to be worn when using super-cooling equipment to prevent frostbite. Methods such as super-cooling or heating should be used only when specifically called for by the equipment or bearing manufacturer. In the event that the equipment manufacturer calls for these methods to be used in the repair manual, it is critical to follow the directions exactly to prevent damage or injury.

Hot Mounting

Hot mounting is used to achieve a transverse interference fit. Use this method when directed by the equipment manufacturer. This method is achieved by heating the inner race when press fit onto a shaft or heating the housing when press fit into the housing. Extreme care should be taken, as this method can cause personal injury, fire, and damage to bearings, shafts, and housings if done improperly or if the equipment or bearing manufacturer instructions are not followed. It is not recommended to use a heating torch, as this applies a great deal of heat to a small area and is a major fire hazard. When using these methods, wear the proper PPE and follow the tool and equipment manufacturer's safety precautions and instructions. It will be important to heat parts to a specific temperature and not overheat them; otherwise, the part's metallurgical structure will start to change and the part will likely fail prematurely. To prevent this, you should use a heat crayon that will indicate when the part is at a specific temperature. The crayon is rubbed on the part, and when

FIGURE 4-34 Temperature indicator sticks are made in multiple temperature ranges and are an excellent way to determine when a part reaches a certain temperature.

FIGURE 4-35 A variety of methods can be used to heat bearing for installation but the induction method is the best.

it melts, you know it is at the right temperature. Heat crayons come in different heat ranges (**FIGURE 4-34**).

A variety of methods can be used to heat bearings for installation. Propane torches, although they are not recommended, are still frequently used. This method of heating a bearing is highly inaccurate and can lead to premature bearing failure, so again, it is not recommended. A more reliable method of heating bearing is by using an oven because the temperature can be controlled and monitored. The most popular and the recommended method, which comes from bearing manufacturers, is induction heating. When heating bearings, it is important that the temperature does not exceed the maximum recommended by the manufacturers. Heat crayons like the one pictured in Figure 4-34 will melt at specific temperatures and indicate when the bearing has been heated sufficiently. **FIGURE 4-35** shows a variety of heating systems.

Once again, too much heat or heat in too small of an area can permanently change the metallurgical properties of the metal. This may not be visible, but it will weaken the parts and reduce

their service life. Methods such as super-cooling or heating should be used only when specifically called for by the equipment or bearing manufacturer. In the event the equipment manufacturer calls for these methods to be used in the repair manual, it is critical to follow the directions exactly to prevent damage or injury.

General Bearing Installation Steps

The following process will provide general guidelines for how to install a bearing. As always, refer to the specific equipment manufacturer's service and repair manual for specific instructions. In addition, follow **SKILL DRILL 4-2** to practice your knowledge and skills in selecting the best tools for your bearing and seal replacement.

1. Work only with clean tools, clean hands, and clean surroundings to avoid damage to the bearing.
2. The shaft and housing bore should be inspected and verified to be clean, smooth, and free of any imperfections on the surfaces that the bearing or seals will contact.
3. Leave bearings in their packaging until they are ready for installation. Do not wash off the lubricant covering them unless it is incompatible with the lubricant the bearing will operate in.
4. Lubricate the race being press fit and the shaft or housing seat on which it will sit with the same lubricant the bearing will operate in.
5. Start the bearing on the shaft or in the housing with the rounded corner of the race going on first.
6. Using the bearing installation tool, apply uniform force only to the press-fit portion of the bearing. Ensure the tool is square and not at an angle.
7. Never hammer directly on races or rollers. Do not use a wooden or soft metal mallet, as chips and splinters may enter the bearing.
8. Use the minimum amount of force needed to seat the bearing.
9. Drive the bearing solidly up against the shoulder of the shaft and/or housing.
10. Lubricate the bearing prior to installation.

► Adjusting Bearing Preload

K04003

When tapered roller bearings are installed, they are required to be **preloaded**, which ensures the rollers are in full contact of the races all the way around the bearing. Applying a preload removes all the internal clearance, or space, between rollers and races in the bearings. When there is space, or clearance, between the bearing rollers and raceway, it has a negative preload. This is because there is no load, or force, on the bearing internal rollers and raceway. When the internal clearances in the bearing are zero, it has zero preload. All solid materials have some amount of crush, or elasticity to them—even hard metals. Because of this, you can create negative internal clearance in a bearing. This condition is having a preload, or force, on the bearing. So, a positive preload means the bearing has a negative amount of internal clearance between the rollers and raceway.

Of course, we don't want to crush the rollers and raceway by having too much preload. So, the right amount of preload is critical to proper bearing operation. Too little or too much preload may result in bearing damage, shaft damage, high heat and friction, and increased rolling resistance. Tapered roller bearing preload adjustment could involve using nuts, spacer sleeves, deformable sleeves (also called crush sleeves), adding or removing shims, and/or a fastener torquing procedure. The goal of this procedure is to ensure every roller is supporting an equal part of the load. To confirm this, a specific rolling resistance must be created that equates to proper bearing preload. It is important throughout the bearing adjustment procedure to lubricate the rollers and to rotate the component to allow proper bearing seating in order to get an accurate reading. Preload measurement is usually accomplished by using a fish scale to directly measure the pounds or kilograms of force required to rotate the supported component, or using by a torque wrench. The equipment manufacturer will publish specifications on the amount of preload and the procedures to adjust it in the repair and service manual. The specific steps to adjust preload depend

SKILL DRILL 4-2 Selecting and Using the Proper Bearing and Seal Installation Tools

As with most repairs, one of the most important things is using the right tool for the right job. Bearings and seals can be easily damaged by using the incorrect tools or methods for installation or removal. Have you, or has another technician you know, ever installed a bearing using a punch and a hammer or used a flame torch to install bearings?

Let's see if you can use the correct tools for the job.

1. Select a piece of heavy-duty equipment currently in your shop for service or repair.
2. Gather the needed information and look up in the manufacturer's service and repair literature the required tools, and removal and installation procedure for one of the wheel end

bearing and seals. You could also look up an outer axle bearing or another shaft bearing.

3. Ask yourself these questions:
 - What tools are required to perform this job correctly?
 - Do I have the correct or equivalent tools specified by the equipment manufacturer?
 - Is the bearing a press-fit one? If so, is the outer or inner race, or are both races, press fit?
 - Will I need any accessories to my bearing and seal tools to work properly?
 - Will I need to do any adjustments once the bearing installation is complete?

on the equipment/bearing manufacturer. Generally, the technician will do the following:

1. Take initial measurements of preload or internal clearances to determine the appropriate crush sleeve, shims, and so on to use.
2. Assemble the bearings and components, rotating several times to seat the bearings.
3. When assembling a pinion bearing cage manufacturers will publish a specification as to how much pressure should be placed on the assembly with a press, (this pressure will represent the load placed on the bearings after final assembly).
4. Check the preload by measuring the turning resistance of the bearings using the equipment manufacturer's procedures (commonly by using a fish weight scale (FIGURE 4-36)).
5. The weight scale will indicate the pounds pulled, multiply this by the distance in inches from the center of the component to the edge where the string for the scale is attached, (this distance represents the lever length being used to turn the component); the result will be the inch pound rolling torque or preload of the component.
6. Compare actual measurement to specifications, and determine if adjustments are needed.
7. Adjust and repeat until preload is within specifications.

► Removal, Installation, and Replacement of Seals

K04004

Seals require much the same tools and techniques for installation as bearings. Just like bearings, the specific removal and installation process depends on the type of seal. Most seals will be damaged upon removal, or are one-time-use and must be replaced when removed for disassembly. Some of the more common seal removal tools are seal picks, and a seal removal tool (FIGURE 4-37).

Extreme care must be taken when installing and replacing seals to ensure they are installed properly and not damaged.

FIGURE 4-36 Measuring bearing preload using a torque wrench and a fish weight measuring scale.

Seals can be delicate and easily damaged. Keep new seals in their original container until just prior to installation to prevent damage. Seals should be lubricated with a compatible lubricant at the sealing and lip surfaces to prevent damage during installation. Seal installation can require tools as simple as a set of small picks or more specialized tools like a **seal driver** (FIGURE 4-38).

O-Rings

Any time components are removed for repair or service, it is common practice to replace all O-ring-type seals. This is a cheap way to ensure there won't be any seal-related leaks. The groove that the O-rings fit into must be clean and free of corrosion to ensure a proper and long-lasting seal. O-ring seals should be lubricated when installed, and sometimes grease is used to hold the seal in place upon installation. You should also be sure they aren't twisted. Extra measures taken during installation to prevent the new O-ring from being damaged will reduce the likelihood of a time-consuming repair of a brand new seal leaking upon repair verification. A good set of **seal picks** will help with removing and installing O-ring seals.

FIGURE 4-37 Seal removal tools: **A.** Set of seal picks. **B.** Seal removal tool.

FIGURE 4-38 Seal installation tools.

Lip-Type Seals

Lip-type seal installation can be tricky, and care needs to be taken not to damage the seal on installation. Depending on the type of lip-type seal, there could be several different installation procedures. Urethane or elastomeric lip-type seals that are installed on the inside of hydraulic cylinder head will need to be carefully folded without creasing the seal. This will effectively decrease the inside diameter of the seal, allowing it to fit inside the cylinder bore and then expand into the seal groove.

Metal-supported lip-type seals will usually be installed with an interference fit into a recess in the component. The metal backing or support for this type of seal will usually have a soft vinyl-like coating on it, which will fill any inconsistencies between the metal backing and the component it is installed into. The ideal way to install a metal-supported lip-type seal is with a seal installer tool that will center itself on the seal and apply pressure only to the outside diameter of the metal support. This tool will likely have a solid part in the center that allows the technician to drive the seal in with a hammer. Care needs to be taken when installing this type of seal to install it evenly and to stop driving when the seal has bottomed out. Removing lip-type seals could involve using heel bars or pry bars or involve drilling holes in the metal support and inserting screws that are pried on or pulled out with a slide hammer and a coarsely threaded adapter. Grooves or recesses for lip-type seals should be clean and dry before seal installation. The seal lip should be lubricated before component assembly.

Some lip-type seals will have their lips ride on a **wear sleeve**. The wear sleeve is a thin piece of hardened steel that is designed to wear over time and should be replaced when the seal is replaced. This prevents the rotating motion from wearing on the actual components. Wear sleeves are installed by gently heating them and using a special tool to slide them over the components they are protecting or pressed on by using special tools. When the sleeve cools, it will shrink onto the component for a tight fit. Engine crankshafts will commonly use wear sleeves. Some lip-type seals and wear sleeves come as an assembly and must not be separated. They will require a special installation tool, and they are used mainly for rear crankshaft seals on engines.

Metal-to-Metal Face Seals

These are sometimes called duo-cone seals. This type of seal (shown in **FIGURE 4-39**) is most commonly used for wheel seals and or final drive seals. Duo-cone seals can be reused provided that they don't exceed recommended wear specifications and don't show other signs of failure, such as pitting or cracks. Wear is measured with duo-cone seals by seeing how wide the contact pattern is between the two metal parts. Duo-cone toric O-ring seals must be completely dry and clean during installation; however, the metal faces must be lubricated before component assembly. Special installation tools are recommended to be used for installing these seals.

Piston Ring-Type Seals

This style of seal is typically found in turbochargers and used to seal the turbo shaft. They are also found in torque converters and transmissions. They consist of a simple hardened metal ring

FIGURE 4-39 A metal-faced type of dynamic seal, sometimes called a duo-cone seal.

that creates a dynamic seal between two rotating parts and are very similar to piston rings. Care must be taken when installing this type of seal to not overstretch them or scratch them.

Many of the same techniques and tools for proper bearing removal and installation can be used with seals. Seals can require replacement when specified by the equipment manufacturer during the disassembly of other components or when they have failed. A seal can be considered to have failed when it is no longer performing its intended function. For a seal that is used to seal gases, when any amount leaks past the seal, it is considered to have failed. For a seal that is used to seal liquids, there can be several stages of failure: a seal can be weeping, have a leak to a drip, or have completely failed. How severe a seal leak can be before requiring replacement depends on the application and equipment manufacturer. For a seal that is used as a dust seal, to keep contaminants out, it would be considered to have failed when it is not

keeping dust and contaminants out. A failed dust seal can allow foreign material to enter and contaminate internal components, such as bearings. Failed seals can also lead to cross-contamination of fluids from one machine component to another, eventually causing damage to other parts. Replacing a seal is much cheaper, and less time-consuming, than allowing a problem to persist and damage other parts and systems. Replace seals when

- seal replacement is required as part of another service procedure, as specified in the equipment manufacturer's service and repair manual
- the seal is leaking, or not performing its function
- the seal is damaged during removal or fails a visual inspection prior to reassembling components.

► Causes of Seal and Bearing Failures

K04005

Bearing Failures

Bearings rarely fail because of a design or manufacture defect. Machine design engineers select bearings for use based on normal operating loads and conditions, regular maintenance being done, and an expected lifespan. If the machine is operated, maintained, and repaired according to the manufacturer's recommendations, the machine's bearings should last several thousand hours. They usually fail because of one of the following causes:

- **Overloading:** For example, if a rock truck is constantly overloaded, this extra weight will overload the machine's wheel bearings and shorten their life (**FIGURE 4-40**) shows an overloaded bearing failure.
- **Over-speeding:** For example, if a machine gets stuck and one wheel receives all the speed from the differential, it will be over-speeding one wheel bearing and could cause it to fail.
- **Contamination:** Bearings need a specific type of clean lubrication and will fail if the lubrication is compromised because of contamination from dirt, water, metal, coolant, air, fuel, or other fluids (**FIGURE 4-41**) show contamination failure.

FIGURE 4-40 Bearing damage due to overloading.

- **Misalignment:** If the bearing isn't designed to handle misalignment, failure will occur if there are excessive and mis-directed loads created because of this.
- **Lack of lubrication:** Low oil levels or lack of grease will cause shortened bearing life. Without lubrication, the metals will smear against one another (**FIGURE 4-42**).
- **Improper installation:** For example, bearings that are misaligned, improper tools damaging bearings or races, bearings not fully seated in housing or on shaft, and bearings with improper preload adjustment will fail prematurely (**FIGURE 4-43**).

It is important to look for external causes when a bearing fails prematurely. If the type of failure or an inspection of the failed bearing indicates a possible external cause, investigate it thoroughly. A new bearing that is installed when there was another cause for the bearing to fail will only result in a repeat failure. Until the condition that caused the bearing to fail is corrected, replacement bearings will fail again.

FIGURE 4-41 Bearing damage due to foreign debris contamination. This could be due to a failed seal allowed contaminants from the outside in or a mechanical failure in an inside component.

FIGURE 4-42 Bearings require lubrication. A loss or lack of lubrication will soon lead to catastrophic bearing failure and may cause additional damage as well.

FIGURE 4-43 Bearing damage due to improper installation is the most preventable cause. A hammer and drift punch is not a proper tool for installing most bearings.

Seal Failures

Seals can fail for numerous reasons. The most common cause of seal failure is excessive heat. Excess heat will cause the seal to shrink and harden, eventually leading to a leak. Here are some of the possible causes of seal failure:

- excessive heat
- use of fluids or additives incompatible with the seal
- shaft or housing misalignment
- shaft or housing sealing surfaces have imperfections
- shaft is bent or out of round
- bearing failure causing excess shaft movement
- excessive vibration
- improper installation tools or techniques
- inadequate lubrication
- foreign debris damage.

Just as in bearing failure analysis, seal failure may be caused by external factors. When replacing a failed seal, inspect the old one to determine the cause of failure. If you suspect something other than normal seal wear, look for other causes. If a seal has failed due to an external cause, such as excess shaft movement, replacing only the seal will not correct the problem.

► Gasket Servicing

K04006

Gaskets can be very simple in design and made from one type of material. They may need to seal almost no pressure, or they can be very complex multi-material structures that could be required to seal several thousand psi of pressure, such as when used for sealing between an engine block and its cylinder head. Gaskets can be made from materials such as paper, cork, plastic blends, steel, rubber blends, steel rubber laminations, and composite fiber blends. Gaskets should be designed to seal two stationary parts and the pressures that are built up inside one or more compartments. Although the components that a gasket is sealing are stationary the gasket must allow for slight relative

FIGURE 4-44 Gaskets come in all shapes, sizes, and materials.

movement created by temperature and or pressure changes. They should also allow for slight surface imperfections. See **FIGURE 4-44** for an example of an assortment of gaskets.

Most gaskets should be installed on clean, dry surfaces. This will require a thorough cleaning procedure of old gasket material. Appropriate care and PPE usage should be practiced when removing old gaskets. Care must be taken when cleaning old gasket material off metal surfaces. If you are too aggressive with your cleaning procedure, it is possible to remove metal from the component being cleaned. Some cleaning tools you may use for this include scrapers, knives, emery cloth, sandpaper, and fiber pads on pneumatic die grinders.

► Types and Applications of Sealants

K04007

Sealant is a substance that is applied in a liquid form to fill a gap between components, which then hardens to create a seal. Many people also refer to sealant as a liquid gasket. Sealant can fill crevices and sharp corners to create a seal in ways that a solid pliable gasket cannot. The heavy-duty equipment technician will become very familiar with many types of sealants, if they have not already. Each type of sealant is specifically engineered to operate in certain conditions. Sealants are selected and defined according to their characteristics. To select the appropriate sealant for a certain application, the following factors must be considered:

- What is the temperate range that the sealant must perform in?
- What solid materials will the sealant need to adhere to, to form a seal?
- What liquids and/or gases will the sealant be exposed to?
- What pressure range will the sealant need to perform under?
- How large of a gap, will the sealant need to fill to form a seal?
- How long does the sealant need to last?

- Does the sealant need to be flexible or hard?
- Are there restrictions on the type of material that the sealant can be composed of (for example, silicone-based sealants)?
- Where will the sealant be used (engine oil pan, transmission pan, gearbox cover, water pump, etc.)?

As you can see, selecting the correct sealant for an application involves many factors. Therefore, in most circumstances, the equipment manufacturer specifies the sealant to use for each application. The heavy-duty equipment technician should follow the instructions in the equipment manufacturer's service and repair manual when selecting the correct sealant. Failure to follow the manufacturer's requirements may result in using the improper sealant. A sealant that is improper for the application may not seal at all, may fail in a very short time, may not cure, or may cause contamination to other systems and parts, resulting in component damage. It is much easier and more economical to use the correct sealant in the first place than to have to disassemble and reseal components later. Sealants are used in most of the major systems in heavy-duty equipment, such as engines, transmissions, drivetrains, and body applications. In general, there are three types of sealants used in engine sealing applications (FIGURE 4-45):

1. RTV (room temperature vulcanizing) sealant
2. anaerobic sealant
3. pipe joint compound.

RTV sealant is pliable and the most commonly used sealant for most automotive and heavy-duty equipment applications. It is not suitable for extremely high temperatures, such as are found in exhaust systems or cylinder head gaskets. Anaerobic sealant can cure without the presence of oxygen. This is required because in some applications, once components are assembled the sealant will not be exposed to the atmosphere. Because of this if anaerobic sealant was not used, the sealant could not cure properly. Pipe joint compound can be used to seal connections in alternate-fueled engines. It is typically used with propane systems to seal threaded components that are under low gas pressure.

FIGURE 4-45 There are many different types of sealants.

► TECHNICIAN TIP

Sensors and sealants sometimes don't mix! Because of their nature, some material from a sealant will inevitably enter the systems, fluids, and gases that the sealant is exposed to, directly or indirectly. Because of this, the material the sealant is made of must be compatible with its application. For example, some types of silicone RTV sealant will damage oxygen sensors. Even when the sealant is used in an area of the engine not exposed to the exhaust fumes directly, the silicone will contaminate the oxygen sensors eventually. Silicone RTV used on an oil pan gasket will contaminate the oil, eventually entering the combustion chambers and then out the exhaust, contaminating the oxygen sensors. Follow the equipment manufacturer's specifications for the type of sealant to be used in each application.

► Fluids and Lubricants

K04008, S04001

Fluids are used in equipment for many purposes. Most fluids will be needed for lubricating system components. The fluid will create a film between parts that are moving in relation to each other, which prevents metal-to-metal contact of the components. Transmission fluid, for example, will keep shafts floating in a film of oil. This is called hydrodynamic suspension. Other fluids, like engine coolant, are used for cooling components, while yet others are needed for both lubrication and cooling. Hydraulic and brake systems use fluid for transferring energy, cooling, sealing, and lubricating.

It is very important to use the proper **viscosity**, type, and quality of fluid for each system. All systems on a piece of equipment are designed to be used with a fluid made to a certain standard. Most equipment manufacturers will have their own brand of fluids that have been made to their standards, and they will strongly recommend using their brand in their machines. They may also give minimum standards that an aftermarket fluid must meet if the owner wants to use another kind of fluid. If a piece of equipment is still under warranty, it is wise to use whatever fluids the equipment manufacturer recommends and keep records that can prove this fact in case there is a warranty dispute. Warranty claims can be denied based on the use of wrong fluids.

Fluid Viscosity

Fluid viscosity refers to a fluid's resistance to flow. When it comes to recommending proper fluid viscosities, equipment manufacturers will provide a viscosity chart with the equipment repair and maintenance guide. Fluid viscosity requirements will mandate changing the **ambient air temperature** (outside air temperature in the immediate vicinity of the machine). Generally speaking, as the ambient temperature where the equipment is working warms up from winter to summer, thicker fluids should be used, and the opposite is true from summer to winter. If the fluid is to stay in the compartment for 500 hours, you must try to roughly predict the highest and lowest temperatures that the equipment will be operating in and use the recommended viscosity for that temperature range.

Fluid viscosity is measured by standards set by two organizations: **SAE (Society of Automotive Engineers)** and **ISO (International Organization for Standards)**. Both organizations have developed test methods that measure the rate of fluid flow through a fixed orifice when it is at a certain temperature. The faster it flows, the lower its viscosity is or the thinner it is. It will be given a lower number that relates to the lesser amount of time it took to flow through the orifice. The opposite is true for a thicker fluid, and the longer it takes, the higher its viscosity number. To compare two fluids that you may be familiar with, think of water as a very low viscosity fluid and shampoo as a very high viscosity fluid. Typical SAE viscosity numbers for machine fluids range from SAE 0W to SAE 60. An SAE number that has a W following it has been tested at a lower temperature; the W stands for winter. ISO viscosity numbers (measured in VG, or viscosity grade) range from ISO VG 22 to ISO VG 100.

See **FIGURE 4-46** for a range chart of fluid viscosity to ambient air temperature, for several fluid types.

Fluid Viscosity Ratings

Gear oil has a different numbering system, which starts at SAE 75W and goes to SAE 140. Some fluids are called multi viscosity, such as 10W30 engine oil. They will act like a lower viscosity fluid when cold, which means they flow better but will resist thinning out when they warm up. This is done with additives called viscosity improvers. If a fluid thins out too much, it won't provide the proper oil film between rotating components. The product's viscosity rating will be identified on the product label (**FIGURE 4-47**). Here are some typical viscosity numbers for different fluid types:

- diesel engine oil—SAE 10W30 or 15W40
- hydraulic fluid—SAE 10W or ISO 32
- power shift transmission fluid—SAE30
- axle fluid—SAE 95
- final drive fluid—SAE 50
- brake fluid—10W.

FIGURE 4-46 Many types of heavy-duty equipment specify using different viscosity fluids at ambient air temperatures.

FIGURE 4-47 Viscosity ratings on multiple fluid types.

Fluid Additives

Equipment manufacturers will generally recommend that no aftermarket additives need to be added to any fluids for a machine. There are some exceptions to this, such as an axle that has friction material in it for an anti-spin (limited slip) device.

There are countless fluid additives available that their manufacturer's claim will improve performance, increase fuel economy, stop leaks, and lower emissions (**FIGURE 4-48**). In most cases, these additive manufacturers have not put in the engineering, research, and independent testing needed to determine the long-term

FIGURE 4-48 Some examples of the many type of fluid additives available; most are not recommended.

effects of these products on all the equipment types they could be used in. If the equipment manufacturer is not willing to allow these additives into their equipment during the warranty period, when they are responsible for paying for repairs, then you may want to think twice about using them when you, your customers, or your company are responsible for paying for the repairs.

Fluid Properties

Besides the viscosity grading of fluids, there are many other important properties a fluid should have before it can be used. Always check with the manufacturer's maintenance information to see the required fluid properties for any system. Other machine fluids and their properties follow.

Diesel Fuel

The type of diesel fuel recommended for a machine is determined by the manufacturer. Improper fuel used in a machine can cause filter plugging and many other fuel system component problems. Diesel fuel used in heavy equipment can fall under two classifications: (Number 1) diesel that has a lower viscosity and is used in the winter and (Number 2) diesel that is slightly higher in viscosity and used in the summer. Diesel fuel suppliers will adjust the viscosity of fuels as seasonal temperatures change.

Sulfur content in diesel fuel is very important with today's low emission engines. Most engines designed for North American use, now require the use of ULSD (ultra-low sulfur diesel) with a sulfur content of less than 0.0015% (15 ppm). Some fuels used in the past had sulfur contents over 1%.

Biodiesel has gained popularity lately and has been approved by most manufacturers to use if it meets recognized standards. The organic part of biodiesel is limited to no more than a small percentage (5–20%) of the diesel fuel content. Biodiesel is labeled B5 or B20 to identify the organic content. See **FIGURE 4-49** for how low sulfur diesel is identified at the fueling pump.

Water in diesel fuel can cause very expensive problems and should be kept to a specified percentage minimum. This

FIGURE 4-49 If the equipment requires low sulfur diesel fuel, it must be used to prevent damage. Additionally, if your equipment is capable of using biodiesel, you can use it to conserve resources.

is done with water separators and fuel tank drains. Fuel tanks on machines should be filled up as much as possible to reduce condensation buildup.

Engine Oil

Engine oil must do the following 10 things:

1. permit easy starting when cold
2. provide lubrication to moving engine parts and prevent wear
3. prevent metal-to-metal contact in pressurized friction bearings
4. protect against corrosion and rust
5. keep engine parts clean and move contaminants away from critical areas
6. reduce combustion chamber deposits
7. resist forming varnish and sludge deposits
8. cool engine parts by absorbing heat
9. seal in combustion chamber gases
10. not produce foam.

The ideal engine oil for any diesel engine will use a base oil combined with the proper additives, to address these 10 requirements. Using the oil recommended by the engine manufacturer in a machine is crucial for achieving the maximum service life from engine components that are in contact with the oil, as well as being able to maximize oil change intervals.

Some machines will come from the factory with break-in oil that will need to be changed at 250 hours of use.

Proper engine oil type is recommended by two characteristics. The first is viscosity, and the second is its rating according to **API (American Petroleum Institute)** or another engine oil property rating organization. Most major engine manufacturers will create their own oil standard. API has set engine oil standards for many years. They started in the mid-1900s by setting minimum standards that engine oil should meet. They looked for properties

FIGURE 4-50 Ensure that the API rating on the engine oil used at least meets the equipment manufacturer's minimum requirements.

like antioxidation, antifoaming, and anticorrosion to help engine manufacturers get the most life and efficiency out of their engines. The first designation for gas engines was SA (S stands for spark ignition), and the first for diesel was CA (C standing for compression ignition). As engine technology moved forward, it put different demands on the engine oil, and every few years SAE would create a new minimum standard. As the new standards came out, the letter designation would change. Today's diesel engines will need from a CG-4 to a CJ-4 spec oil. See **FIGURE 4-50** to see the label API ratings of diesel engine oil.

Using the proper oil for today's low emission engines is critical to ensuring their longevity and staying within the low emission regulations. Synthetic engine oil can be used if it meets the recommended standards and is the proper viscosity. The main advantage of synthetic is its cold weather low viscosity or ease of flow ability in low temperatures and resistance to oxidation at high temperatures. All new oil is backward compatible, meaning the newest specification can be used for older engines as well.

Engine Coolant

Most diesel engine coolant is made up of three things: glycol, water, and additives. Water alone should never be used in a cooling system except in case of emergency. A minimum of 30% glycol/70% water should be used, and a more common mix is 50/50. Distilled or de-ionized water should be used if needed to top up but the safest way is to add a premixed coolant solution, which is usually 50/50.

Coolant additives will protect the metal surfaces that the coolant is exposed to by preventing foaming, rust, corrosion, liner pitting, and scale buildup. Additives will get depleted as the engine accumulates hours and will need to be topped up at certain service intervals.

Glycol in the coolant helps prevent freezing and boiling of the coolant. A 50/50 concentration will give a freeze protection down to -34°F (-36°C) and a boil protection of up to 223°F (106°C). Overconcentration of glycol (70% and higher) will start to decrease these properties. There are two main types of coolant used: coolants with an ethylene glycol base and those with a propylene glycol base.

Many machines come with long-life coolant commonly called ELC or extended-life coolant that will be able to stay in the machine from 6,000 to 12,000 hours with only additive top-offs. See **FIGURE 4-51** to see an example of a diesel engine coolant.

Engine coolant can also be sampled and analyzed. This is also good practice, especially if long-life coolant is expected to be in the system for five or more years.

FIGURE 4-51 Diesel engine coolant.

Hydraulic Fluid

It has been said that the most important component in a hydraulic system is the hydraulic fluid. Hydraulic fluid has to clean, cool, lubricate, and seal the components it operates in, but its main function is to transfer energy. Hydraulic fluid in a high-pressure system will be compressed (roughly 1% for every 2,000 psi) and relaxed constantly. This will put an extra strain on the fluid.

The most common type of hydraulic fluid is the petroleum-based type and is usually called mineral oil, hydraulic oil, or just oil. It is the most economical and easiest to find. Some machine manufacturers will allow you to use or will recommend that diesel engine oil be used in the hydraulic system since many of the requirements that an engine oil must meet apply to hydraulic oil.

You will quite often see the letters AW associated with hydraulic oil. This stands for antiwear, and the oil will have a higher zinc and phosphorus content. Other additives in the oil will include detergents, rust inhibitors, antioxidants, and anti-foaming agents.

To make a hydraulic fluid have a more stable viscosity over a wide range of temperatures, it will have viscosity improvers (VI) added.

Some machines can use water-based or glycol-based hydraulic fluids. These fluids are used for their fire-resistant properties. There are also biodegradable ester synthetic-based hydraulic fluids that are used for their environmentally friendly properties. These alternative fluids are much more expensive

FIGURE 4-52 Biodegradable hydraulic fluid.

than mineral oil-based hydraulic fluids and will need special consideration for service intervals and filter compatibility. For example, bio-hydraulic oil is much more sensitive to water content and must be changed if water content exceeds 0.1%. See **FIGURE 4-52** to see a container of biodegradable hydraulic fluid.

Power Shift Transmission Fluid

Power shift, or automatic, transmissions have friction discs in them that require specific additives to allow them to function properly and last. Friction discs that run in fluid need an oil with friction modifiers added to it. Almost all power shift transmissions will have a torque converter driving it. A torque converter uses the fluid as a power transfer medium that relies on hydrodynamic principles. The fluid in a power shift transmission also needs to float rotating shafts, transfer heat, and provide anticorrosion, antioxidation, and antiwear functions. Using the incorrect fluid or having the transmission fluid become contaminated can damage the friction discs and other parts inside the transmission. This could require a complete teardown and rebuild of the entire transmission. One power shift fluid specification that is required to be met by many manufacturers is Caterpillar TO-4 (**FIGURE 4-53**).

Axle and Final Drive Fluid

If the axle or final drive doesn't have friction materials in it that will be exposed to the lubricating fluid, it will likely require an oil classed as a gear oil. A common oil used for axles and final drives is classified as GL-5. Limited slip-type final drives with friction clutch discs usually require a limited slip additive to be added to the fluid.

Brake Fluid

Machines that have an automotive type of hydraulic brake system (master cylinder and wheel cylinders or calipers) will require a glycol-based brake fluid that will be either DOT 3

FIGURE 4-53 Caterpillar TO-4 transmission fluid.

or DOT 5 specification. Brake fluid must be able to withstand extremely high temperatures and be able to absorb moisture (hygroscopic). Machines that use petroleum-based brake fluid may use oil from its hydraulic system or have its own brake oil reservoir. It will likely be a low viscosity fluid, like 10W.

Grease

Grease is used to lubricate moving parts that don't have their own lubrication system. Grease is a lubricant that is usually used for slower moving parts exposed to high forces. It needs to be replenished regularly, because it will get squeezed out from between the parts it is lubricating and dry out.

Grease needs to do the following:

1. reduce friction and wear
2. provide corrosion protection
3. protect bearings from water and contaminants
4. resist leakage, dripping, and throw off
5. resist change in structure and consistency during usage
6. be compatible with seals.

Base materials for grease are mostly either petroleum, mineral, or synthetic with calcium, aluminum, or lithium as the thickener. Additives are then combined with the base material to provide all the qualities mentioned above. Grease additives may include

- oxidation inhibitors—which prolong the life of a grease
- EP (extreme pressure) agents—which guard against scoring and galling
- anticorrosion agents—which protect metal against attack from water
- antiwear agents—which prevent abrasion and metal-to-metal contact.

Grease specifications are mostly established by the **NLGI (National Lubricating Grease Institute)**. The required grease for machine lubrication can vary widely, but the most common type of grease used for lubricating the slow-moving high-force parts such as excavator boom, stick, and bucket pins is EP 2. Grease viscosity ranges from 000 (thinnest for extreme cold) to 6 (which is solid).

FIGURE 4-54 A wide variety of types of grease exist.

The most common grease viscosities are 1 (like soft margarine) and 2 (like soft peanut butter). Grease used in automatic greasers will be thinner (0 or 00) because it must flow through hoses, tubes, and valves. See **FIGURE 4-54** to see a variety of greases.

Follow **SKILL DRILL 4-3** to see if you can identify and select the correct fluids and lubricants.

As a heavy-duty equipment technician, you will be spending a lot of your time servicing bearings, seals, gaskets, and fluids for the equipment you service. These items are some of the most critical parts on any piece of heavy equipment. Failure to perform required maintenance, performing repairs incorrectly, or not detecting failures early with these parts can result in costly damage to other, more expensive parts and systems. Performing quality and proper repairs in these areas will reduce the probability of costly and embarrassing comeback repairs on the equipment you are servicing.

SKILL DRILL 4-3 Selecting the Correct Fluids

The most important thing about servicing fluids is selecting the correct fluid for the correct application. Incorrect fluids can result in expensive damage to major systems and parts, such as engines, transmissions, brakes, and hydraulic systems.

1. Select a piece of heavy-duty equipment currently in your shop for service or repair.
2. Gather the needed information and look up in the manufacturer's service and repair literature the proper fluid types, ratings, specifications, and capacities for each of the following fluids:
 - engine oil
 - transmission fluid

- coolant
- hydraulic fluid
- final drive/axle gear oil.

3. Determine whether the manufacturer specifies that any fluids depend on other factors like ambient air temperature, type of use, hours or miles/kilometers on equipment, etc.
4. Now, research whether your shop has the correct fluids in stock or where they can be sourced from.

► Wrap-Up

Ready for Review

- ▶ The largest single factor in premature bearing failures is improper installation.
- ▶ When installing an interference-fit bearing, place the driving forces onto the press-fit race or both the press-fit and slip-fit races simultaneously.
- ▶ Look for external causes for bearing and/or seal failure when they failure prematurely.
- ▶ When removing and reinstalling old bearings or seals, carefully inspect them and replace if they show signs of failure.
- ▶ Be careful not to install lip-type seals backward; this will cause premature failure.
- ▶ Bearing heating and super-cooling methods of interference-fit installation should be done only when

called for in the equipment manufacturer's service and repair manual.

- ▶ New bearings and seals should be kept in their packaging until just prior to installation, to protect them.
- ▶ Some equipment manufacturers will specify different fluid viscosities and types depending on the ambient temperature outside where the equipment works.
- ▶ Always look up the equipment manufacturer's required types of fluids, lubricants, and sealants to ensure a proper repair and that no damage was incurred due to incorrect fluids and sealants.
- ▶ When a bearing preload adjustment is required with a repair, you must follow the equipment manufacturer's instructions carefully to achieve the correct amount or preload.
- ▶ Use safety glasses when removing and installing bearings.

Key Terms

adaptor plates An accessory for bearing removal and installations tools. The plates surround a shaft, and provide a surface for puller jaws to attach while also ensuring all the forces are placed at the inner press-fit race of the bearing.

arbor press A small hand operated press that uses mechanical leverage to apply a compressive force to a ram

National Institute for Automotive Service Excellence (ASE) An independent, nonprofit organization that seeks to improve the quality of automotive repair by testing and certifying automotive service professionals.

ambient temperature The temperature of the surrounding environment.

API (American Petroleum Institute) An organization in the United States that sets standards and standardized tests for petroleum products.

axial (thrust) Axial, or thrust, loads always act along the centerline of a shaft. So, they can only apply a force that moves a shaft in or out along its axis.

ball bearings A type of bearing which uses spherical balls as the rolling elements within a raceway, to reduce friction between moving parts. They are typically mounted between a shaft and stationary housing.

bearing A machine element that constrains movement to only the desired direction and reduces friction between moving parts.

bearing driver A tool used to install bearings, and sometimes seals, that applies a uniform amount of force to a targeted area of the bearing to drive the press-fit surface of a bearing onto a shaft or into a housing.

blind hole bearing puller A bearing removal tool that is used when the outer bearing race is press fit into a housing and can only be removed by placing a tool through the center, or blind, hole and pulling from the inside.

coefficient of friction A dimensionless physical value that describes the amount of force needed for one surface to slide against another. A ratio of the force needed to move one surface against another, divided by the force (or pressure) between the two surfaces. A higher value means the two surfaces have a greater amount of friction, or resistance, to movement between them.

cylindrical roller bearings Bearings that feature cylindrical rolling elements to reduce friction between moving parts. Roller bearings will have an inner race, outer race, bearing cage, and rollers. The axis of the rollers is parallel to the shaft. They are designed to carry heavy radial loads, not axial loads.

dial indicator A device for precision measurements used to measure small variations, such as end play, movement in a bearing, or run-out.

dynamic Objects that are dynamic are moving or changing.

friction bearing A plain bushing, or friction bearing, also called a plain bearing is a mechanical element used to reduce friction between rotating shafts and stationary support members or housings. They contain no rolling elements and are often lubricated with pressurized lubricant.

friction fit An interference fit, also called a press fit or friction fit, is a means of fastening two parts together so that they are in direct contact with one another and are held in place only by friction or by the tightness of the fit.

gland A recess, or gap, in a part where a seal or O-ring is placed to form a seal when two parts are brought together.

hot mounting A method of bearing installation in which heat is used to expand a bearing, and then the bearing is placed onto a shaft, where it cools and contracts. The bearing will then have a transverse interference fit.

hydraulic press A machine that uses a hydraulic cylinder to generate a compressive force.

interference fit An interference fit, also called a press fit or friction fit, is a means of fastening two parts together so that they are in direct contact with one another and are held in place only by friction or by the tightness of the fit. There is negative clearance between the interference-fit parts, so they must be pressed or forced together.

ISO (International Organization for Standards) An international body which sets standards for members, typically in engineering, mechanical, automotive, and aerospace areas.

linear Linear motion is a motion in a single dimension along a straight line.

Material Safety Data Sheet (MSDS) Same as safety data sheet (SDS).

mechanical bearing packer A tool that uses mechanical force to push grease into all a bearing's external and internal parts. Used to easily *pack* bearings with grease.

needle bearings Bearings that are characterized by their thin (small diameter), long, and numerous roller elements.

NLGI (National Lubricating Grease Institute) An industry organization in the United States that sets standards and rating for grease products.

Occupational Safety and Health Administration (OSHA) A U.S. federal government agency created to provide national leadership in occupational safety and health.

Personal Protective Equipment (PPE) Safety equipment designed to protect the technician, such as safety boots, gloves, clothing, protective eyewear, and hearing protection.

plain bearing A plain bushing, or friction bearing, also called a plain bearing is a mechanical element used to reduce friction between rotating shafts and stationary support members or housings. They contain no rolling elements and are often lubricated with pressurized lubricant.

plain bushings A plain bushing, or friction bearing, also called a plain bearing is a mechanical element used to reduce friction between rotating shafts and stationary support members or housings. They contain no rolling elements and are often lubricated with pressurized lubricant.

plain spherical bearings The plain spherical bearing consists of an inner spherical ring, placed within an outer spherical ring and locked together so that the inner ring is held captive within the outer ring in the axial direction only.

preload A condition in which a bearing's internal clearances are completely removed by pressing the bearing against a shaft and/or housing, so that there is negative internal clearance. The bearing therefore has a *load* applied at all times to the rolling elements and raceway.

press fit An interference fit, also called a press fit or friction fit, is a means of fastening two parts together so that they are in direct contact with one another and are held in place only by friction or by the tightness of the fit. There is negative clearance between the interference-fit parts, so they must be pressed or forced together.

pulling plates An accessory for bearing removal and installation tools. The plates surround a shaft and provide a surface for puller jaws to attach to while also ensuring all the forces are placed at the inner press-fit race of the bearing.

race The area in which the rolling elements on a rolling bearing ride; also called a raceway.

raceway The area in which the rolling elements on a rolling bearing ride; also called a race.

radial Radial loads act from the center of a circle or shaft outwards. So, the load, or force, is always at a right angle to the circumference of the circle they are acting from.

radial shaft seals A seal used between cylindrical moving elements such as a shaft and a bore or housing; also called lip seals.

repair and maintenance manual A manual published by an equipment manufacturer with information on how to safely and properly maintain, repair, and troubleshoot equipment.

roller bearings Bearings that feature cylindrical rolling elements to reduce friction between moving parts. Roller bearings will have an inner race, outer race, bearing cage, and rollers. They may be straight or tapered roller bearings.

society of Automotive Engineers (SAE), SAE International A U.S.-based, globally active professional association and standards developing organization for engineering professionals in various industries, including automotive; mobile, off-road equipment; commercial truck; and aerospace. It sets industry standards and regulations.

seal A device used to join two or more parts together and prevent the leakage of liquids or gases and the introduction of contaminants.

slip fit A slip fit is when two parts fit together with positive clearance between them so that they will slip over one another.

spherical roller bearings Bearings that are characterized by their barrel-shaped rollers. The rollers are narrow at the ends, and they bulge in the middle like a wooden barrel. They will handle some axial load and can tolerate misalignment of the two separated components.

static Objects that are static are not moving or are not changing.

tapered roller bearings Bearings that are characterized by the conical (cone-shaped) rollers that are arranged in at a *tapered* angle to the shaft, so that the rollers form a cone shape around the shaft.

technical safety bulletins Documents periodically published and distributed by an equipment manufacturer that identify a safety risk or hazard and how to properly control the risk or hazard.

thrust loads Axial, or thrust, loads always act along the centerline of a shaft. So, they can only apply a force that moves a shaft in or out along its axis.

viscosity The state of being thick, sticky, or semi-fluid in consistency due to internal friction.

wear sleeve The wear sleeve is a thin piece of hardened steel placed over a rotating shaft that is designed to wear over time, and it should be replaced when the seal is replaced.

Review Questions

- Some bearings will have a cage as part of their assembly that will
 - help distribute oil evenly.
 - keep dirt away from the rollers.
 - help preload the bearing.
 - keep the rollers or balls separated.
- When installing some bearings, a fish scale is used to
 - help torque the nut properly.
 - measure the rolling resistance after it has been preloaded.
 - weigh the balls or rollers before they are installed.
 - weigh the torque wrench to make sure it's calibrated.
- What must all gaskets allow for when creating a seal between two parts?
 - Temperature changes that create part movement
 - Negative pressure spikes
 - Highly corrosive fluids
 - Fastener de-torquing
- Fluid viscosity is determined by
 - boiling the fluid and measuring the thickness.
 - pouring the heated fluid through a fixed orifice.
 - freezing the fluid and measuring the thickness.
 - vaporizing the fluid and measuring the density.
- True or False. A flame torch is an acceptable method to heat a bearing for a hot mount interference fit?
 - True
 - False
- API ratings for diesel engine oil start with a "C." What does the letter C stand for?
 - Compression
 - Combustion
 - Centigrade
 - Combination
- A roller bearing is designed to support mostly which type/s of load/s?
 - Radial load
 - Axial load
 - Both radial and axial loads
 - horizontal loads
- A typical ball bearing is designed to support mostly which type/s of load/s?
 - Radial load
 - Axial load
 - Both radial and axial loads
 - horizontal loads

9. A taper roller bearing is designed to support mostly which type/s of load/s
- Radial load
 - Axial load
 - Both radial and axial loads
 - horizontal loads
10. Which of the following is not a type of o-ring seal?
- X-ring
 - Square ring
 - D-ring
 - C-ring

ASE Technician A/Technician B Style Questions

1. Technician A says that the bearing puller should be attached with the jaws gripping the outside of the bearing and the forcing screw against the end of the shaft, to pull the inner press-fit bearing race off the shaft. Technician B says that you should use a pulling plate behind the bearing and attach the puller jaws to the plate. Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
2. Technician A says that you should use a wooden hammer and a soft brass punch to lightly tap the bearing on, alternating around the circumference in a star pattern to distribute the forces driving the bearing on. Technician B says that you should use a length of old pipe, whose diameter fits the press-fit bearing race, and a hammer to drive the bearing on. Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
3. Technician A says grease that is labeled EP means it can withstand extreme pressure. Technician B says automatic greasers will use a lower viscosity grease. Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
4. Technician A says that a diesel engine not rated to use B20 biodiesel could be damaged by using B20. Technician B says that an older diesel engine not rated to use ultra-low sulfur diesel fuel could be damaged if fueled with that type of fuel. Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
5. Technician A says that engine oil ratings are formulated by the Society of Automotive Engineers (SAE). Technician B says that engine oil ratings are established by the American Petroleum Institute (API). Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
6. Technician A says that the *tapered* in tapered roller bearings refers to the tapered, cone-style layout of the bearing rollers around the center of the bearing. Technician B says that the *tapered* in tapered roller bearings refers to the fact that the rollers themselves are cone-shaped or tapered. Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
7. Technician A says that an oil bath heater is acceptable to use for heating any bearing type for a hot mounting. Technician B says that it is always preferable to use a super-cooling method to shrink the shaft, as this has less chance of damaging the heat temper of parts. Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
8. Technician A says that sealant should be used where a gasket makes a very sharp curve on the engine oil pan, to achieve a better seal. Technician B says that you must make sure the chemical makeup of the sealant is compatible with that area of the engine. Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
9. Technician A says that for a tapered shaft bearing installation, you should drive the bearing up the shaft as far as it will go until it has no looseness in the bearing. Technician B says that there must be some amount of internal looseness in the bearing to run properly. Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
10. Technician A says that anaerobic sealant can cure without the presence of oxygen. Technician B says that anaerobic sealant means that you must have oxygen present for the sealant to cure. Who is correct?
- Technician A
 - Technician B
 - Both A and B
 - Neither A nor B

CHAPTER 5

Tools and Fasteners

Knowledge Objectives

After reading this chapter, you will be able to:

- **K05001** Describe and explain the purpose and use of hand- and air-operated tools.
- **K05002** Identify tools and fasteners using correct industry terminology.

Skills Objectives

After reading this chapter, you will be able to:

- **S05001** Select, use, and maintain hand- and air-operated tools.
- **S05002** Select and use measuring tools according to their proper purpose, function, and procedure.

Attitude Objectives

After reading this chapter, you will be able to:

- **A05001** Organize and correctly store tools and fasteners with respect to good housekeeping.

► Introduction

The design of **mobile off-road equipment (MORE)** is the result of a number of engineering sciences. Not only are they structurally complex, but they also combine a number of unique characteristics, components, and ancillary equipment that unite to allow them to perform specialized tasks in some of the harshest environments. Engine blocks and components are made of metals that are able to withstand very high temperatures and stresses. Lubricants keep the engine with its cooling properties functioning smoothly by reducing friction on moving parts and allowing the engine to perform reliably. The vehicle body is made of materials that are durable and strong enough to withstand harsh conditions and repeated use. In addition to understanding the basic materials used in MORE construction and the fluids used to keep them operating safely and efficiently, technicians must know which tools to use for different types of service applications. Tools and equipment are vital components of an efficient and effective shop and/or field service operation. Nearly all repair tasks involve the use of some sort of tool or piece of equipment.

The vast majority of tools are designed to remove and install fasteners. Fasteners are designed to hold two or more components together. All types of MORE have hundreds and even thousands of parts and thousands of fasteners. These parts must be able to be assembled, from multiple components into one machine. In addition, these machines must be serviceable, which means the components must be able to be removed and reinstalled. This requires the use of fasteners that allow for the easy assembly, removal, and installation of parts. Much of the work that goes into a part replacement is involved with the fasteners that attach the part to the rest of the equipment. Because of this, it is vitally important for the MORE technician to be familiar with fasteners, their uses, types, and special considerations.

In this chapter, you will learn about the basic tools and fasteners used in MORE and how to identify the correct tool and fasteners for a particular application, how to use the tool correctly, and how to clean, inspect, and store it properly after using it.

History of Tools and Fasteners

The use of simple tools can be traced back as far as Stone Age humans. In fact, tools were a critical part of the everyday life of early humans. This includes tools used as weapons and for leather working. Later, when humankind began to establish

agriculture-based societies, tools used for agriculture, irrigation, weaving, and stone working were essential. Fasteners of various types have been used since the same time, although they have evolved to a more advanced degree. Early fasteners were as simple as wooden pegs hammered into holes in a piece of wood to form a joint and later various types of metal nails. While the screw principle was first documented by Archimedes around 200 B.C.E., modern mass-produced threaded fasteners did not appear until the late 1700s. This invention was critical to the Industrial Revolution. The invention of a process to mass-produce high-quality metal threads in fasteners allowed larger, stronger, faster, and more precise machines. In fact, without the ability to create threaded fasteners, modern equipment and machinery would not be possible. Since the first introduction of humankind to simple tools and fasteners, we have advanced significantly to include power- and computer-operated tools (**FIGURE 5-1**).

► Purpose and Usage of Tools

K05001

A **tool** is a physical item used to do something or accomplish a goal. The purpose of a tool is to allow a person to perform a task that would be more difficult, time-consuming, dangerous, or impossible without that tool. Tools can be used to tighten or

FIGURE 5-1 An example of advanced tools: a power-operated tool used by NASA in the assembly and servicing of the Hubble Space Telescope.

You Are the Mobile Heavy Equipment Technician

You are required to go out to a field service location to perform a repair on a piece of MORE that will require the removal and reinstallation of several parts to access the component that requires replacement.

1. What considerations should you make to ensure you select the proper tools to bring with you to the equipment site?
2. How can you determine whether any specialty tools or equipment may be required for the repair, before traveling to the job site?
3. Once at the equipment site, what (if any) preparation should you take to ensure that tools and fasteners do not get lost or misplaced?
4. After the repair is complete, what measures should you take to properly clean the repair site?
5. After the repair is completed, how can you ensure that no tools or equipment are left behind?

loosen fasteners, remove or install **press-fit** parts, or measure physical quantities such as distance, air or hydraulic pressure, vacuum, weight, force, torque, electrical voltage, power, current, and many others. When the proper tools are used for the proper applications, they can make accomplishing a task much easier. When used improperly, they can be a safety hazard.

Every tool has a proper application and a proper way to use it. The following paragraphs will provide some basic knowledge on the proper use of tools. A tool is used properly when it is used in the intended manner so that its user can accomplish its stated goal safely.

Basic Tool Preparation and Safety

Although it is important to be trained on the safe use of tools and equipment, it is even more critical to have a safe attitude. A safe attitude will help you avoid being involved in an accident. Technicians who think they will never be involved in an accident will not be as aware of unsafe situations as they should be, and such an attitude could lead to accidents. Therefore, as we discuss the various tools and equipment you will encounter in the shop, pay close attention to the safety and operation procedures. Tools are a technician's best friend, but if used improperly, they can injure or kill.

Work Safe and Stay Safe

Always think "safety first" whenever you use tools. There is nothing more important than your personal safety. If you use tools (both hand and power) incorrectly, you could potentially injure yourself and others. Always follow equipment and shop instructions, including the use of recommended **personal protective equipment (PPE)**. One of the characteristics of MORE is that they are big and heavy. Because of this, many of the tools used to service MORE are big, heavy, operated with a great deal of torque, and potentially dangerous. Accidents take only a moment to occur but can take a lifetime to recover from. You are ultimately responsible for your own safety, so remember to work safe and stay safe.

Handling and Using Tools Safely

Tools must be safely handled and used to prevent injury and damage. Always inspect tools prior to use, and never use damaged tools or any replacement tool. Check the manufacturer's documentation and the shop procedures or ask your supervisor if you are uncertain about how to use any tool. Inspect and clean tools when you have finished using them. Always return tools to their correct storage location. Some tools are heavy or awkward to use, so seek assistance if necessary, and use correct manual handling techniques.

► Tools and Equipment Fundamentals

K05001, S05001, S05002, A05001

Every tool is designed to be used in a certain way to do the job safely. It is critical to use a tool in the way it is designed to be used and to do so safely. For example, a screwdriver is designed

to tighten and loosen screws, not to be used as a chisel. **Ratchets** are designed to turn **sockets** and are not to be used as a hammer. Think about the task you are undertaking, select the correct tools for the task, and use each tool for what it was designed for.

Identifying Metric and Imperial Designations

Many tools, measuring instruments, and fasteners come in metric and imperial sizes. Tools are identified as metric or imperial by markings that identify their sizes or by the increments on measuring instruments. Fasteners bought new will have their designation identified on the packaging. Other fasteners may have to be measured by a ruler or **vernier caliper** to identify their designation. Manufacturers' charts showing thread and fastener sizing will assist in identifying imperial or metric sizing.

To identify metric or imperial designations, follow these steps:

1. Examine the component, tool, or fastener to see whether any marking identifies it as metric or imperial. Manufacturer specifications and shop manuals may be referred to and may identify components as metric or imperial.
2. If no markings are available, use measuring devices to gauge the size of the item and compare thread and fastener charts to identify the sizing. Inch-to-metric conversion charts will assist in identifying component designation.

► TECHNICIAN TIP

The correct tools make you much more efficient and effective in performing your job. Without tools, it would be very difficult to carry out machine repairs and servicing. This is the reason many technicians invest thousands of dollars in their personal tools. If purchased wisely, tools will help you perform more work in a shorter amount of time, thereby making you more productive. Therefore, think of your tools as an investment that pays for itself over time.

Types of Tools

In this section, we will examine the following types of tools:

- hand-operated tools
- measurement tools
- air-operated (pneumatic-operated) tools.

► TECHNICIAN TIP

If you work in the field, it is extremely important to bring the proper tools with you to the job site. Failing to bring needed tools will increase repair time and cause you to have to make inconvenient return trips to retrieve the proper tools. The selection of your basic tool loadout will come only through experience performing service on the specific type of MORE equipment you work on. However, you can identify any specialty tools that may be required by reviewing the equipment manufacturer's service information for the expected repair before departing for the job site. You will find the added time establishing this habit will save you a lot of time and frustration in the long run.

Hand Tools

A large percentage of your personal tools will be hand tools. These are available in a variety of shapes, sizes, and functions, and like all tools, they extend your ability to do work. Over the years, manufacturers have introduced new fasteners, wire harness terminals, quick-connect fittings for fuel and other lines, and additional technologies that require their own specific types of hand tools. This means that technicians need to add tools to their toolboxes all of the time.

Wrenches **Wrenches** (often referred to as spanners in some countries) are used to tighten and loosen nuts and bolts, which are two types of fasteners. There are three commonly used wrenches: the **closed-end wrench**, the **open-end wrench**, and the **combination wrench**. The closed-end wrench fits fully around the head of the bolt or nut and grips each of the six points at the corners, just as a socket does. This is precisely the kind of grip needed if a nut or bolt is very tight, and it gives you a better chance of loosening very tight fasteners. Its grip also makes the closed-end wrench less likely than the open-end wrench to round off the points on the head of the bolt (**FIGURE 5-2A**).

The ends of closed wrenches are bent or offset so that they are easier to grip, and they have different-sized heads at each end. One disadvantage of the closed-end wrench is that it can be awkward to use once the nut or bolt has been loosened a little, because you have to lift it off the head of the fastener and move it to each new position. The open-end wrench is open on the end, and the two parallel flats grip only two points of the fastener (**FIGURE 5-2B**). Open-end wrenches usually have either different-sized heads on each end of the wrench or heads the same size but with different angles. The head is at an angle to the handle and is not bent or offset, so it can be flipped over and used on both sides. This is a good wrench to use in very tight spaces as you can flip it over at the end of its travel and get a new angle, so that the head can catch new points on the fastener. Although an open-end wrench often gives the best access to a fastener, it should not be used if the fastener is extremely tight, as this type of wrench grips only two points. If the jaws flex slightly or the flats do not fit tightly around them, the wrench could suddenly slip when force is applied. This slippage can round off the points of the fastener. The best way to tackle a tight fastener is to use a closed-end wrench to break the bolt or nut free; then use the open-end wrench to finish the job. The open-end wrench should be used only on fasteners that are no more than firmly tightened. The combination wrench has an open-end head on one end and a closed-end head on the other (**FIGURE 5-2C**). Both ends are usually the same size, so the closed end may be used to break the bolt loose and the open end to turn the bolt. Because of its versatility, this is probably the most popular wrench for technicians.

A variation on the open-end wrench is the **flare-nut wrench**, also called a flare-tubing wrench (**FIGURE 5-2D**). This type of wrench enables a better grip than the open-end wrench does because it grabs all six points of the fastener instead of only two.

However, because it is open on the end, it is not as strong as a closed-end wrench. The partially open sixth side allows the wrench to be placed over tubing or pipes so that it can be used to turn the tube fittings. Do not use the flare-nut wrench on extremely tight fasteners because the jaws may spread, damaging the nut.

Another open-end wrench is the **open-end adjustable wrench, or crescent wrench**. This wrench has a movable jaw that by turning an adjusting screw can be adjusted to fit any fastener within its range. It should be used only if other wrenches are not available, because it is not as strong as a fixed wrench and thus could slip off of and damage the heads of tight bolts or nuts. Still, it is a handy tool to have because it can be adjusted to fit most fastener sizes.

A **ratcheting closed-end wrench** is a useful tool for some applications because it can be repositioned without having to be removed (**FIGURE 5-2E**). It has an inner piece that fits over and grabs the fastener points and is able to rotate within the outer housing. A ratcheting mechanism allows it to rotate in one direction and lock in the other direction. In some cases, the wrench simply needs to be flipped over to be used in the opposite direction. In other cases, it has a lever that changes the direction from clockwise to counterclockwise. Be careful not to overstress this tool by using it to tighten or loosen very tight fasteners, as the outer housing is not very strong.

There is also a **ratcheting open-end wrench**, which uses no moving parts. One of the sides is partially removed so that only the bottom one-third remains to catch a point on the bolt. The normal side works just like a standard open-end wrench. The shorter side of the open-end wrench catches the point on the fastener so that it can be turned. When moving the wrench to get a new bite, the wrench is pulled slightly outwards, disengaging the short side while leaving the long side to slide along the faces of the bolt. The wrench is then rotated to the new position and pushed back in so that the short side engages the next point. This wrench, like other open-end wrenches, is not designed to tighten or loosen tight

FIGURE 5-2 **A.** Closed-end wrench. **B.** Open-end wrench. **C.** Combination wrench. **D.** Flare-nut wrench. **E.** Ratcheting closed-end wrench.

fasteners, but it does work well in blind places where a socket or ratcheting closed-end wrench cannot be used.

The **pipe wrench** grips pipes and can exert a lot of force to turn them (**FIGURE 5-3A**). Because the handle pivots slightly, the more pressure put on the handle to turn the wrench, the more the grip tightens. The jaws are hardened and serrated, so increasing the pressure increases the risk of marking or even gouging the metal of the pipe. The jaw is adjustable, so it can be threaded in or out to fit different pipe sizes. Pipe wrenches are also available in different lengths, allowing increased leverage to be applied to the pipe.

A specialized tool called a **filter wrench** grabs fuel, oil, and coolant cartridge-type filters. The filter wrench provides extra leverage to remove a filter when it is tight (**FIGURE 5-3B**). These are available in various designs and sizes. Some filter wrenches are adjustable to fit many filter sizes. Note also that a filter wrench can be used to remove and tighten a filter. Always check the markings on a filter to determine how much farther a filter is rotated with a wrench after it has been hand-tightened.

Sockets Sockets are very popular because of their adaptability and ease of use (**FIGURE 5-4**). Sockets are a good choice when the top of the fastener is reasonably easily accessible. The socket fits onto the fastener snugly and grips it on all six corners, providing the type of grip needed on any nut or bolt that is extremely tight. They are available in a variety of configurations, and technicians usually have a lot of sockets so that they can access a multitude of tight places. Individual sockets fit a particular size of nut or bolt, so they are usually purchased in sets.

Sockets are classified by the following characteristics:

- metric or imperial depending on the equipment manufacturer
- size of drive used to turn them— $\frac{1}{2}$ inch, $\frac{3}{8}$ inch, and $\frac{1}{4}$ inch are most common, while 1 inch and $\frac{3}{4}$ inch are common on HD off-road equipment

FIGURE 5-3 A. Pipe wrench. B. Oil-filter wrench.

FIGURE 5-4 The construction of a socket.

- number of points—6 and 12 are most common
- depth of socket—shallow and deep are most common
- thickness of wall—standard and impact are most common, while thicker-walled sockets are used for air-operated impact wrenches.

Sockets are built with a recessed square drive that fits over the square drive of the ratchet or other driver. The size of the drive determines how much twisting force can be applied to the socket. The larger the drive, the larger the twisting force. Small fasteners usually need only a small torque, so do not use a drive larger than you need because too large a drive may impede the socket's access to the bolt. For fasteners that are really tight, an impact wrench exerts a lot more torque on a socket than turning it by hand. Impact sockets have thicker walls than standard wall sockets and have six points, so they can withstand the forces generated by the impact wrench as well as grip the fastener securely.

Both 6-point and 12-point sockets fit the heads of hexagonal shaped fasteners. Also, 4-point and 8-point sockets fit the heads of square-shaped fasteners. Because 6-point and 4-point sockets fit the exact shape of the fastener, they have the strongest grip on the fastener, but they fit on the fastener in only half as many positions as a 12-point or 8-point socket.

► TECHNICIAN TIP

When using a socket or wrench, if the nut or bolt feels like it is beginning to round the corners off, stop and change to a different socket. Try a socket with fewer points of grip, like a 6-point or a 4-point socket. This will grip better and prevent rounding off the nut or bolt.

Another factor in accessing a fastener is the depth of the socket. If a nut is threaded quite a distance down a stud, then a shallow-length socket will not fit far enough over the stud to reach the nut. In this case, a deep socket will usually reach the nut (**FIGURE 5-5A**). Turning a socket requires a handle. The most common socket handle, the ratchet, makes easy work of tightening or loosening a nut when not a lot of pressure is involved (**FIGURE 5-5B**). A ratchet may be set to turn in either direction and does not need much room to swing. It is built to be convenient, not super strong, so too much pressure could damage it. For heavier tightening or loosening, use a breaker bar because it gives the most leverage (**FIGURE 5-5C**).

When that is not available, a **sliding T-handle** may be more useful. With this tool, both hands may be used, and the position of the tee piece is adjustable to clear any obstructions when turning it (**FIGURE 5-5D**). The connection between the socket and the accessory is made by a square drive (**FIGURE 5-5E**). The larger the drive, the heavier and bulkier the socket. The $\frac{1}{4}$ inch drive is for small work in difficult areas. The $\frac{3}{8}$ inch drive accessories handle a lot of general work where torque requirements are not too high. The $\frac{1}{2}$ inch drive is required for all-round service. The $\frac{3}{4}$ inch and 1 inch drives are required for large work with high-torque settings.

Many fasteners are located in positions where access can be difficult. There are many different lengths of extensions available to allow the socket to be on the fastener while extending the drive point out to where a handle can be attached (**FIGURE 5-5F**). A **speed brace** or speeder handle is the fastest way to spin a fastener on or off a thread by hand, but it cannot apply much torque to the fastener; therefore, it is used mainly to remove a fastener that has already been loosened or to run the fastener onto the thread until it begins to tighten (**FIGURE 5-6A**). A **universal joint** takes the turning force that needs to be applied to the socket through an angle (**FIGURE 5-6B**).

Pliers **Pliers** are a hand tool designed to hold, cut, or compress materials (**FIGURE 5-7**).

They are usually composed of two pieces of strong steel joined at a fulcrum point, with jaws and cutting surfaces at one

FIGURE 5-5 A. Deep socket. B. Ratchet. C. Breaker bar. D. Sliding T-handle. E. Square drive. F. An extension with a handle attached.

FIGURE 5-6 A. Speed brace. B. Universal joint.

FIGURE 5-7 Pliers are used for grasping and cutting.

end and handles designed to provide leverage at the other. There are many types of pliers, including slip-joint, combination, arc joint, needle-nosed, and flat-nosed. Quality **combination pliers** (**FIGURE 5-8A**) are the most commonly used pliers in a shop. They are made from two pieces of high-carbon or alloy steel. They pivot together so that any force applied to the handles is multiplied in the strong jaws. Some pliers provide a powerful grip on objects, whereas others are designed to cut. Combination pliers can do both, which is why they are the most commonly used (please note that pliers are job-specific). Combination pliers offer two surface—one for gripping flat surfaces and one for gripping rounded objects—and two pairs of cutters. The cutters in the jaws should be used for softer materials that will not damage the blades. The cutters next to the pivot can shear through hard, thin materials, such as steel wire or pins.

Most pliers are limited by their size in what they can grip. Beyond a certain point, the handles are spread too wide or the jaws cannot open wide enough, but **slip joint pliers** overcome that limitation with a movable pivot. These are often called **Channellocks**, after the company that first made them. These pliers have parallel jaws that allow you to increase or decrease the size of the jaws by selecting a different set of channels. They

are useful for a wider grip and a tighter squeeze on parts too big for conventional pliers.

There are a few specialized pliers in most shops. **Needle-nosed pliers**, which have long, pointed jaws, can reach tight spots or hold small items that other pliers cannot. For example, they can pick up a small bolt that has fallen into a tight spot (**FIGURE 5-8B**). **Flat-nosed pliers** have an end or nose that is flat and square; in contrast, combination pliers have a rounded end. A flat nose makes it possible to bend wire or even a thin piece of sheet steel accurately along a straight edge (**FIGURE 5-8C**).

Diagonal-cutting pliers (**FIGURE 5-8D**) are used for cutting wire or cotter pins. Diagonal cutters are the most common cutters in the toolbox, but they should not be used on hard or heavy-gauge materials, because the cutting surfaces will be damaged. End-cutting pliers, also called **nippers**, have a cutting edge at a right angle to their length (**FIGURE 5-8E**). They are designed to cut through soft metal objects sticking out from a surface.

Snap ring pliers have metal pins that fit in the holes of a snap ring. Snap rings can be of the internal or external type. If internal, then internal snap ring pliers compress the snap ring so that it can be removed from and installed in its internal groove (**FIGURE 5-8F**). If external, then external snap ring pliers are used to remove and install the snap ring in its external groove (**FIGURE 5-8G**).

SAFETY TIP

Always wear safety glasses when working with snap rings, as the rings can easily slip off the snap ring pliers and fly off at tremendous speeds, possibly causing severe eye injuries.

TECHNICIAN TIP

When applying pressure to pliers, make sure your hands are not greasy; if they are, they might slip. Select the right type and size of pliers for the job. As with most tools, if you have to exert almost all your strength to get something done, then you are using either the wrong tool or the wrong technique. If the pliers slip, you will get hurt. At the very least, you

will damage the tool and what you are working on. Pliers get a lot of hard use in the shop, so they do get worn and damaged. If they are worn or damaged, they will be inefficient and can be dangerous. Always check the condition of all shop tools on a regular basis.

Locking pliers, also called *vice grips*, are general purpose pliers used to clamp and hold one or more objects (**FIGURE 5-9**). Locking pliers are helpful because they free up one or more of your hands when working; they clamp something and lock themselves in place to hold it. They are also adjustable, so they can be used for a variety of tasks. To clamp an object with locking pliers, put the object between the jaws, turn the screw until the handles are almost closed, then squeeze them together to lock them shut. You can increase or decrease the gripping force with the adjustment screw. To release them, squeeze the release lever and they should then open up.

Cutting Tools **Bolt cutters** cut heavy wire, non-hardened rods, and bolts (**FIGURE 5-10A**). Their compound joints and long handles give the leverage and cutting pressure needed for heavy-gauge materials. **Tin snips** are the nearest thing in the toolbox to a pair of scissors (**FIGURE 5-10B**). They cut thin sheet metal, and lighter versions make it easy to follow the outline of gaskets. Most snips come with straight blades, but if there is an unusual shape to cut, there is a pair with left- or right-hand curved blades. **Aviation snips** are designed to cut soft metals (**FIGURE 5-10C**). They are easy to use because the handles are spring-loaded open and double-pivoted for extra leverage.

Allen Wrenches **Allen wrenches**, sometimes called Allen keys or *hex keys*, are tools designed to tighten and loosen fasteners with Allen heads (**FIGURE 5-11**). The Allen head has an internal hexagonal recess that the Allen wrench fits into. Allen wrenches come in sets, and there is a correct wrench size for every Allen head. They give the best grip on a screw or bolt of all the drivers, and their shape makes them good at getting into tight spots. Care must be taken to ensure that the correct size of Allen wrench is used; otherwise, the wrench and/or socket head

FIGURE 5-8 **A.** Combination pliers. **B.** Needle-nosed pliers. **C.** Flat-nosed pliers. **D.** Diagonal-cutting pliers. **E.** Nippers. **F.** Internal snap ring pliers. **G.** External snap ring pliers.

FIGURE 5-9 Locking pliers.

FIGURE 5-10 A. Bolt cutters. B. Tin snips. C. Aviation snips.

FIGURE 5-11 A typical Allen wrench.

will be rounded off. The traditional Allen wrench is a hexagonal bar with a right-angle bend at one end. They are made in various sizes in both metric and imperial. As their popularity has increased, so too has the number of tool variations. Now Allen sockets and T-handle Allen wrenches are available.

Screwdrivers The correct screwdriver to use depends on the type of slot or recess in the head of the screw or bolt and how accessible it is. Most screwdrivers cannot grip as securely as wrenches, so it is very important to match the tip of the screwdriver exactly with the slot or recess in the head of a fastener; otherwise, the tool might slip, damaging the fastener or the tool and possibly injuring you.

SAFETY TIP

When using a screwdriver, always check where the screwdriver tip could end up if it slipped off the head of the screw. Many technicians who have not taken this precaution have stabbed a screwdriver into or through their hand, thigh, or other body part.

The most common screwdriver has a flat tip, or blade, which gives it the name **flat-tip screwdriver** (FIGURE 5-12A). The tip

FIGURE 5-12 A. Flat-tip screwdriver. B. Phillips tip screwdriver. C. Pozidriv-tip screwdriver.

should be almost as wide and thick as the slot in the fastener so that the twisting force applied to the screwdriver is transferred right out to the edges of the head where it has the most effect. The tip should be a snug fit in the slot of the screw head. Then the twisting force is applied evenly along the sides of the slot. This will guard against the screwdriver suddenly chewing a piece out of the slot and slipping just when the most force is being exerted. Flat-tip screwdrivers are available in a variety of sizes and lengths, so find the right one for the job. If viewed from the side, the tip should taper slightly until the very end, where the tip fits into the slot. If the tip is not clean and square, it should be reshaped or replaced. When you use a flat-tip screwdriver, support the shaft with your free hand as you turn it (but keep it behind the tip). This helps keep the tip square on the slot and centered. Screwdrivers that slip are a common source of damage and injury in shops.

A screw or bolt with a cross-shaped recess requires a **Phillips screwdriver** or a **Pozidriv screwdriver** (FIGURE 5-12B). The cross-shaped slot holds the tip of the screwdriver securely on the head. The Phillips tip fits a tapered recess, whereas the Pozidriv fits into slots with parallel sides in the head of the screw (FIGURE 5-12C). Both a Phillips screwdriver and a Pozidriv screwdriver are less likely to slip sideways because the point is centered in the screw, but again, the screwdriver must be the right size. The fitting process is simplified for these two types of screwdrivers because four sizes are enough to fit almost all fasteners with this type of screw head.

The **offset screwdriver** fits into spaces where a straight screwdriver cannot and is useful where there is not much room to turn it (FIGURE 5-13A). The two tips look identical, but one is set at 90 degrees to the other. This is because sometimes there is room to make only a quarter turn of the driver. Thus the driver has two tips on opposite ends, so that offset ends of the screwdriver can be used alternately.

The **ratcheting screwdriver** is a popular screwdriver handle that usually comes with a selection of flat tips and Phillips tips (FIGURE 5-13B). It has a ratchet inside the handle that turns the tip in only one direction depending on how the slider is set. When set for loosening, a screw can be undone without removing the tip from the head of the screw. When set for tightening, a screw can be inserted just as easily.

An **impact driver** is used when a screw or a bolt is rusted/corroded in place, or overtightened, and needs a tool that can apply more force than the other members of this family (**FIGURE 5-13C**). Screw slots could easily be stripped with the use of a standard screwdriver. The force of the hammer pushing the bit into the screw, and at the same time turning it, makes it more likely that the screw will break loose. The impact driver accepts a variety of special impact tips. Choose the right one for the screw head, fit the tip in place, and then tension it in the direction it has to turn. A sharp blow with the hammer breaks the screw free, and then it can be unscrewed.

Magnetic Pickup Tools, Mechanical Fingers, and Mechanic's Mirrors **Magnetic pickup tools** and **mechanical fingers** are very useful for grabbing items in tight spaces. A magnetic pickup tool is typically a telescoping stick that has a magnet attached to the end on a swivel joint (**FIGURE 5-14A**).

The magnet is strong enough to pick up screws, bolts, and sockets. For example, if a screw is dropped into a tight crevice where your fingers cannot reach, a magnetic pickup tool can be used to extract it. Mechanical fingers are also designed to extract or insert objects in tight spaces (**FIGURE 5-14B**). Because they actually grab the object, they can pick up non-magnetic items, which makes them handy for picking up rubber or plastic parts. They use a flexible body and come in different lengths, but are typically about 12–18 inches (305 to 457 mm) long. They have expanding grappling fingers on one end to grab items, and the other end has a push mechanism to expand the fingers and a retracting spring to contract the fingers. Another tool that comes in handy is a mechanic's mirror. A **mechanic's mirror** is a small mirror on a stick that can be adjusted to view leaks, identify tags, and find dropped parts and tools. It can be placed into areas that are difficult to view or access.

► TECHNICIAN TIP

The challenge is to get the magnet down inside some areas because the magnet wants to keep sticking to the sides. One trick in this situation is to roll up a piece of paper so that a tube is created. Stick that down into the area of the dropped part, then slide the magnet down the tube,

FIGURE 5-13 A. Offset screwdriver. B. Phillips tip screwdriver. C. Pozidriv-tip screwdriver.

FIGURE 5-14 A. Magnetic pickup tools. B. Mechanical fingers.

which will help it get past magnetic objects. Once the magnet is down, you may want to remove the roll of paper.

Hammers Hammers are a vital part of the shop tool collection, and a variety are commonly used. The most common hammer in a shop is the **ball-peen (engineer's) hammer** (**FIGURE 5-15A**). Like most hammers, its head is hardened steel. A punch or a chisel can be driven with the flat face. Its name comes from the ball-peen or rounded face. It is usually used for flattening and **peening** a rivet. The hammer should always match the size of the job, and it is better to use one that is too big than too small.

SAFETY TIP

The hammer you use depends on the part you are striking. Hammers with a metal face should almost always be harder than the part you are hammering. Never strike two hardened tools together, as this can cause the hardened parts to shatter.

Soft-Face Steel Hammers feature a drop forged head specifically designed to mushroom when striking hard base materials; they are gaining popularity for added safety against chipping and spalling, which cause injury.

Hitting chisels with a steel hammer is fine, but sometimes you need to only tap a component to position it (**FIGURE 5-15B**). A steel hammer might mark or damage the part, especially if it is made of a softer metal, such as aluminum. In such cases, a soft-faced hammer should be used for the job. Soft-faced hammers range from very soft, with rubber or plastic heads, to slightly harder, with brass or copper heads. When a large chisel needs a really strong blow, it is time to use a **club hammer** (**FIGURE 5-15C**). The club hammer is like a small mallet, with two square faces made of high-carbon steel. It is the heaviest type of hammer that can be used one-handed. The club hammer is used in conjunction with a chisel to cut off a bolt where corrosion has made it impossible to remove the nut. The most common small-headed mallet in the shop has a head made of hard nylon (**FIGURE 5-15D**). It is a special purpose tool and is often used for moving things into place where it is important

not to damage the item being moved. For example, it can be used to tap a crankshaft, to measure end play, or to break a gasket seal on an aluminum casing.

A **dead-blow hammer** is designed not to bounce back when it hits something (**FIGURE 5-15E**). A rebounding hammer can be dangerous or destructive. A dead-blow hammer may be made with a lead head or, more commonly, a hollow polyurethane head filled with lead shot or sand. The head absorbs the blow when the hammer makes contact, reducing any bounce back or rebounding. This hammer can be used when working on the machine chassis or when dislodging stuck parts.

SAFETY TIP

When using hammers and chisels, safety goggles must always be worn. In addition, watch fingers and hands around hammers and be careful of bounce back. Many embarrassing injuries occur while using hammers.

Chisels The most common kind of chisel is a cold chisel (**FIGURE 5-16A**). It gets its name from the fact that it is used to cut cold metals rather than heated metals. It has a flat blade made of high-quality steel and a cutting angle of approximately 70 degrees. The cutting end is tempered and hardened because it has to be harder than the metals to be cut. The head of the chisel needs to be softer so that it will not chip when it is hit with a hammer. Technicians sometimes use a cold chisel to remove bolts whose heads have rounded off.

A **cross-cut chisel** is so named because the sharpened edge is across the blade width. This chisel narrows down along the stock, so it is good for getting in grooves (**FIGURE 5-16B**). It is used for cleaning out or even making key ways. The flying chips of metal should always be directed away from the user.

TECHNICIAN TIP

Chisels and punches are designed with a softer striking end than hammers. Over time, this softer metal “mushrooms,” and small fragments are prone to breaking off when hammered. These fragments could cause

eye injuries or other penetrative injuries to people in the area. Always inspect chisels and punches for mushrooming and dress them on a grinder when necessary.

Punches **Punches** are used when the head of the hammer is too large to strike the object being hit without causing damage to adjacent parts. A punch transmits the hammer’s striking power from the soft upper end down to the tip that is made of hardened high-carbon steel. A punch transmits an accurate blow from the hammer at exactly one point, something that cannot be guaranteed using a hammer on its own.

When marks need to be drawn on an object such as a steel plate to help locate a hole to be drilled, a **prick punch** is used to mark the points so they will not rub off (**FIGURE 5-17B**).

They can also be used to scribe intersecting lines between given points. The prick punch’s point is very sharp, so a gentle tap leaves a clear indentation. The center punch is not as sharp as a prick punch and is usually bigger (**FIGURE 5-17A**). It makes a bigger indentation that centers a drill bit at the point where a hole needs to be drilled. A **drift punch** is also called a starter punch because you should always use it first to get a pin moving (**FIGURE 5-17C**). It has a tapered shank, and the tip is slightly hollow so that it does not spread the end of the pin and make it an even tighter fit. Once the starter drift has got the pin moving, a suitable pin punch will drive the pin out or in. A drift punch also works well for aligning holes on two mating objects, such as a valve cover and cylinder head. Forcing the drift punch in the hole will align both components for easier installation of the remaining bolts. **Pin punches** are available in various diameters. A pin punch has a long, slender shaft with straight sides. It is used to drive out rivets or pins (**FIGURE 5-18A**). A lot of components are either held together or accurately located by pins. Pins can be pretty tight, and a group of pin punches is specially designed to deal with them. Special punches with hollow ends are called **wad punches** or **hollow punches** (**FIGURE 5-18B**). They are the most efficient tool to make a hole in soft sheet material, such as shim steel, plastic and leather, or (most commonly) in a gasket. When they are used, there should always be

FIGURE 5-15 A. Ball-peen hammer. B. Steel hammer. C. Club hammer. D. Nylon/brass tip mallet. E. Dead-blow hammer.

FIGURE 5-16 A. A cold chisel. B. A cross-cut chisel.

FIGURE 5-17 A. Center punch. B. Prick punch. C. Drift punch.

FIGURE 5-18 A. Pin punch. B. Wad punch. C. Number punch set.

a soft surface under the work, ideally the end grain of a wooden block. If a hollow punch loses its sharpness or has nicks around its edge, it will make a mess instead of a hole. Numbers and letters, like the engine numbers on some cylinder blocks, are usually made with number and letter punches that come in boxed sets (FIGURE 5-18C). The rules for using these punches are the same as for all punches: The punch must be square with the surface being worked on, not on an angle, and the hammer must hit the top squarely.

Pry Bars Pry bars are composed of forged, medium carbon, spring-like steel and are used as levers to move, adjust, or pry. Pry bars are available in a variety of shapes and sizes. Many have a tapered end that is slightly bent, with a plastic handle on the other end (FIGURE 5-19A). This design works well for applying force to tension belts or for moving parts into alignment. Another type of pry bar is the roll bar (FIGURE 5-19B). One end is sharply curved and tapered and is used for prying. The other end is tapered to a dull point and is used to align larger holes, such as transmission bell housings or engine motor mounts. Because pry bars are made

FIGURE 5-19 A. A pry bar. B. A roll bar.

FIGURE 5-20 A gasket scraper.

of hardened steel, care should be taken when using them on softer materials to avoid any damage.

Gasket Scrapers A gasket scraper has a hardened, sharpened blade. It is designed to remove a gasket without damaging the sealing face of the component, when used properly (FIGURE 5-20). On one end, it has a comfortable handle to grip, like a screwdriver handle; on the other end, a blade is fitted with a sharp edge to assist in the removal of gaskets.

The gasket scraper should be kept sharp to make it easy to remove all traces of the old gasket and sealing compound. The blades come in different sizes, with a typical size being 1 inch (25 mm) wide. Whenever you use a gasket scraper, be very careful not to nick or damage the surface being cleaned.

► TECHNICIAN TIP

Many engine components are made of aluminum. Because aluminum is quite soft, it is critical that you use the gasket scraper very carefully so as not to damage an aluminum surface. This can be accomplished by keeping the gasket scraper at a fairly flat angle to the surface. The gasket scraper should also be used only by hand, not with a hammer.

Note: It is extremely important to always point gasket scrapers away from your body and hand while removing gasket material. Stubborn gasket material tends to stick unevenly in areas around bolt holes. Gaskets can break free suddenly and cause the scraper to overshoot the part being cleaned and can cause severe lacerations.

Files Files are cutting devices designed to remove small amounts of material from the surface of a workpiece. Files are available in a variety of shapes and sizes and degrees of coarseness, depending on the material being worked on and the size of the job. Files have a pointed tang on one end that is fitted to a handle. Files are often sold without handles, but they should not be used until a handle of the right size has been fitted. A correctly sized handle fits snugly without working loose when the file is in use. Always check the handle before using the file. If the handle is loose, give it a sharp rap to tighten it up, or if it is the threaded type, screw it on tighter. If it fails to fit snugly, you must use a different handle size.

SAFETY TIP

Hands should always be kept away from the surface of the file and the metal that is being worked on. Filing can produce small slivers of metal that can be difficult to remove from a finger or hand. Clean hands will help avoid slipping and lessen the corrosion caused by acids and moisture from the skin.

What makes one file different from another is not just the shape but also how much material it is designed to remove with each stroke. The teeth on the file determine how much material will be removed (**FIGURE 5-21**). Since the teeth face in one direction only, the file cuts in only one direction. Dragging the file backward over the surface of the metal only dulls the teeth and wears them out quickly.

Teeth on a coarse-grade file are longer, with a greater space between them. A coarse-grade file working on a piece of mild steel will remove a lot of material with each stroke, but it leaves a rough finish. A smooth-grade file has shorter teeth cut more closely together. It removes much less material on each stroke, and the finish is much smoother. The coarse file is used first to remove material quickly, then a smoother file gently removes the last of it and leaves a clean finish on the work. The full list of grades in flat files, from rough to smooth, follows (**FIGURE 5-22**):

- *Rough files* have the coarsest teeth, with approximately 20 teeth per 1 inch (25 mm). They are used when a lot of material must be removed quickly. They leave a very rough finish and must be followed by finer files to produce a smooth final finish.
- *Coarse bastard files* are still coarse files, with approximately 30 teeth per 1 inch (25 mm), but they are not as coarse as

FIGURE 5-21 The teeth on a file.

the rough file. They are also used to rough out or remove material quickly from a job.

- *Second-cut files* have approximately 40 teeth per 1 inch (25 mm) and provide a smoother finish than the rough or coarse bastard file. They are good all-around intermediary files and leave a reasonably smooth finish.
- *Smooth files* have approximately 60 teeth per 1 inch (25 mm) and are a finishing file used to provide a smooth final finish.
- *Dead-smooth files* have 100 teeth per 1 inch (25 mm) or more and are used where a very fine finish is required.

Some flat files are available with one smooth edge and are called *safe-edge files*. They allow filing up to an edge without damaging it. Flat files are fine on straightforward jobs, but you need files that work in some awkward spots as well. A **warding file** is thinner than other files and comes to a point; it is used for working in narrow slots (**FIGURE 5-23A**).

A **square file** has teeth on all four sides, so you can use it in a square or rectangular hole (**FIGURE 5-23B**). A square file can make the right shape for a squared metal key to fit in a slot. A triangular file has three sides (**FIGURE 5-23C**). Because it is

FIGURE 5-22 Common flat files.

FIGURE 5-23 A. Warding file. B. Square file. C. Triangular file.

triangular, it can get into internal corners; it can cut right into a corner without removing material from the sides.

Curved files are either half-round or round. A half-round file has a shallow convex surface that can file in a concave hollow or in an acute internal corner (**FIGURE 5-24A**). The fully round file, sometimes called a *rat-tail file*, can make holes bigger. It can also file inside a concave surface with a tight radius. The thread file cleans clogged or distorted threads on bolts and studs (**FIGURE 5-24B**). Thread files are available in either metric or imperial configurations, so make sure you use the correct file. Each file has eight different surfaces that match different thread dimensions, so the right face must be used. Files should be cleaned after each use. If they are clogged, they can be cleaned by using a file card or file brush (**FIGURE 5-24C**). This tool has short steel bristles that clean out the small particles that clog the teeth of the file. Rubbing a piece of chalk over the surface of the file prior to filing will make it easier to clean.

Hacksaw The hacksaw is used for the general cutting of metals for a crude cut (**FIGURE 5-25**). The frames and blades are adjustable and rated according to the number of teeth and hardness of the saw.

FIGURE 5-24 A. Curved file. B. Thread file. C. File card.

FIGURE 5-25 A hacksaw.

Clamps and Vices The **bench vice** is a useful tool for holding anything that can fit into its jaws (**FIGURE 5-26A**). Some common uses include sawing, filing, or chiseling. The jaws are serrated to give extra grip. They are also very hard, which means that when the vice is tightened, the jaws can mar whatever they grip. To prevent this, a pair of soft jaws may be fitted whenever the danger of damage arises. These are usually made of aluminum or some other soft metal, or they can have a rubber-type surface applied to them. When materials are too awkward to grip vertically in a plain vice, it may be easier to use an **offset vice**. The offset vice has its jaws set to one side to allow long components to be held vertically. For example, a long threaded bar can be held vertically in an offset vice to cut a thread with a die.

A **drill vice** is designed to hold material on a drill worktable. The drill worktable has slots cut into it to allow the vice to be bolted down on the table to hold material securely (**FIGURE 5-26B**). To hold something firmly and drill it accurately, the object must be secured in the jaws of the vice. The vice can be moved on the bed until the precise drilling point is located and then tightened down by bolts to hold the drill vice in place during drilling. The name for the **C-clamp** comes from its shape (**FIGURE 5-26C**). It holds parts together while they are being assembled, drilled, or welded. It can reach around awkwardly shaped pieces that will not fit in a vice. It is also commonly used to retract disc brake caliper pistons. This clamp is portable, so it can be taken to the work.

Taps and Dies **Taps** cut threads inside holes or nuts (**FIGURE 5-27A**). They are usually available in three different types. The first is known as a **taper tap**. It narrows at the tip to give it a good start in the hole where the thread is to be cut. The diameter of the hole is determined by a tap drill chart, which can be obtained from engineering suppliers. This chart shows what hole size must be drilled and what tap size is needed to cut the right thread for any given bolt size. Remember that if you are drilling a $\frac{1}{4}$ inch (6 mm) or larger hole, you should use a smaller pilot drill first. Once the properly sized hole has been drilled, the taper tap can tap a thread right through a piece of steel to enable a bolt to be screwed into it.

The second type of tap is an **intermediate tap**, also known as a **plug tap**, and the third is a **bottoming tap**. They are used to tap a thread into a hole that does not come out the other side of the material, called a blind hole. A taper tap is used to start the thread in the hole, and then the intermediate tap is used, followed by a bottoming tap to take the thread right to the bottom of the blind hole.

A **tap handle** (**FIGURE 5-27B**) has a right-angled jaw that matches the squared end that all taps have. The jaws are designed to hold the tap securely, and the handles provide the leverage for the operator to rotate the tap comfortably to cut the thread. To cut a thread in an awkward space, a T-shaped tap handle is very convenient. Its handles are not as long, so it fits into tighter spaces; however, it is harder to turn and to guide accurately. To cut a brand-new thread on a blank rod or shaft, a die (**FIGURE 5-27C**) held in a **die stock handle** (**FIGURE 5-27D**)

FIGURE 5-27 A. Tap handle, B. taps, C. die, and D. die stock handle.

FIGURE 5-26 A. Bench vice, B. drill vice, and C. C-clamp.

is used. The die may be split so that it can be adjusted more tightly onto the work with each pass of the die, as the thread is cut deeper and deeper until the nut fits properly. The **thread chaser** is also common in the shop. It is hexagonally shaped to fit a wrench, and it is commonly used to clean up threads that are rusty or have been damaged.

Screw extractors are devices designed to remove screws, studs, or bolts that have broken off in threaded holes. A common type of extractor uses a coarse, left-hand tapered thread formed on its hardened body. Usually, a hole is drilled in the center of the broken screw, and then the extractor is screwed into the hole. The left-hand thread grips the broken part of the bolt and unscrews it. The extractor is marked with the sizes of the screw it is designed to remove and the hole that needs to be drilled. It is important to drill the hole carefully in the center of the bolt or stud in case you end up having to drill the bolt out. If you drill the hole off-center, you will not be able to drill it out all the way to the inside diameter of the threads, and removal will become nearly impossible.

Thread Repair **Thread repair** is used in situations where it is not possible to replace a damaged component. This may be because the thread is located in a large, expensive component, such as the engine block or cylinder head, or because parts are not available. The aim of thread repair is to restore the thread to a condition that restores the fastening integrity. It can be performed on internal threads, such as in a housing, engine block, or cylinder head, or on external threads, such as on a bolt.

Many different tools and methods can be used to repair a thread. The least invasive method is to reshape the threads. If the threads are not too badly damaged—for example, if the outer thread is slightly damaged from being started crooked (cross-threaded)—then a thread file may be used to clean them up or a restoring tool may be used to reshape them. Each thread file has eight different sets of file teeth that match various thread pitches. Select the set that matches the bolt you are working on and file the bolt in line with the threads. The file removes any distorted metal from the threads. File only until the bad spot is reshaped. The thread-restoring tool looks like an ordinary tap and die set, but instead of cutting the threads, it reshapes the damaged portion of the thread.

Threads that have substantial damage require other methods of repair. A common method for repairing damaged internal threads is a thread insert. Several manufacturers make thread inserts, and they all work in a similar fashion. The thread

insert is a sleeve that has both an internal and external thread. The internal thread on the insert matches the original, damaged thread size. The hole with the damaged thread is made larger and a fresh, larger-diameter thread is cut. This thread matches the external thread on the insert. The thread insert can then be screwed and secured into the prepared hole. The insert provides a brand-new threaded inside thread that matches the original size.

Pullers Pullers are a very common, universal tool used for removing bearings, bushings, pulleys, and gears (FIGURE 5-28A). Specialized pullers are also available for specific tasks where a standard puller is not as effective. The most common pullers have two or three legs that grip the part to be removed. A center bolt, called a forcing screw or jacking bolt, is then screwed in, producing a jacking or pulling action, which extracts the part. **Gear pullers** come in a range of sizes and shapes, all designed for particular applications (FIGURE 5-28B). They consist of three main parts: jaws, a crossarm, and a forcing screw. There are generally two or three jaws on a puller. They are designed to work either externally around a pulley or internally. The forcing screw is a long, fine-threaded bolt that is applied to the center of the crossarm.

When the forcing screw is turned, it applies many tons of force through the component you are removing. The crossarm attaches the jaws to the forcing screw. There may be two, three,

or four arms. If the crossarm has four arms, three of the arms are spaced 120 degrees apart. The fourth arm is positioned 180 degrees apart from one arm. This allows the crossarm to be used as either a two- or a three-arm puller.

Flaring Tools A **tube-flaring tool** is used to flare the end of a tube so it can be connected to another tube or component. One example of this is where the brake line screws into a wheel cylinder. The flared end is compressed between two threaded parts so that it will seal the joint and withstand high pressures. The three most common shapes of flares are the **single flare**, for tubing that carries low pressures, such as a fuel line; the **double flare**, for higher pressures, such as in a brake system; and the **ISO flare** (sometimes called a bubble flare), which is the metric version used in brake systems (FIGURE 5-29A).

Flaring tools have two parts: a set of bars with holes that match the diameter of the tube end that is being shaped and a yoke that drives a cone into the mouth of the tube (FIGURE 5-29B). To make a single flare, the end of the tube is placed level with the surface of the top of the flaring bars. With the clamp screw firmly tightened, the feed screw flares the end of the tube. Making a double flare is similar, but an extra step is added, and more of the tube is exposed to allow for the folding over into a double flare. A double-flaring button is placed into the end of the tube, and when it is removed after tightening, the pipe looks like a bubble. Placing the cone and yoke over the bubble allows you to turn the feed screw and force the bubble to fold in on itself, forming the double flare. An ISO flare uses a flaring tool made specifically for that type of flare. It is like the double-flare process but stops with the use of the button. It does not get doubled back on itself. It should resemble a bubble shape when you are finished.

Pipe cutters are used to cut a tube to the correct length. These tools produce a cleaner cut because they have fewer burs on the outer surface of the tube (FIGURE 5-29C). A screw on the cutter tightens a cutting wheel that is rotated around the tube. The sharpened cutting wheel of a pipe cutter does the cutting. As the tool turns around the pipe, turning the screw increases the pressure, driving the wheel deeper and deeper through the pipe until it finally cuts through. There is a larger version that is used for cutting exhaust pipes.

Riveting Tools There are many applications for blind rivets, and various rivet types and tools may be used to do the riveting. **Pop-rivet guns** are convenient for the occasional riveting of light materials (FIGURE 5-30). A typical pop or **blind rivet** has a body, which forms the **finished rivet** and a **mandrel**, the latter of which is discarded when the riveting is completed (FIGURE 5-31). It is called a blind rivet because there is no need to see or reach the other side of the hole in which the rivet goes to do the work. In some types, the rivet is plugged shut so that it is waterproof or pressure-proof. The rivet is inserted into the riveting tool, which when squeezed, pulls the end of the mandrel back through the body of the rivet. Because the mandrel head is bigger than the hole through the body, it swells out as it comes through the body. Finally, the mandrel head will snap off under the pressure

FIGURE 5-28 A. Puller. B. Gear puller.

FIGURE 5-29 **A.** Single flare, double flare, and ISO flare. **B.** Components of a flaring tool. **C.** Tubing cutter.

and fall out, leaving the rivet body gripping the two sheets of material together.

Measurement Tools

Precision Measuring Tools MORE technicians are required to perform a variety of measurements while carrying out their job. This requires knowledge of what tools are available and how

FIGURE 5-30 Pop rivet guns.

FIGURE 5-31 Anatomy of a blind, or pop, rivet.

to use them. Measuring tools can generally be classified according to what type of measurements they can make. A measuring tape is useful for measuring longer distances and is accurate to a millimeter or fraction of an inch (**FIGURE 5-32A**). A steel rule is capable of accurate measurements on shorter lengths, down to a millimeter or a fraction of an inch (**FIGURE 5-32B**). Precision measuring tools are accurate to much smaller dimensions: a micrometer, for example, can accurately measure down to $\frac{1}{1000}$ of a millimeter (0.001 mm) in some cases.

► TECHNICIAN TIP

The metric, also called the International System of Units (SI), and imperial systems are two sets of standards for quantifying weights and measurements. Each system has defined units. For example, the metric system uses millimeters, centimeters, and meters, whereas the imperial system uses inches, feet, and yards. Conversions can be undertaken from one system to the other. For example, 25.4 mm is equal to 1 inch, and

FIGURE 5-32 A. Measuring tape. B. Steel rule.

304.8 mm is equal to 1 foot. Tools that make use of a measuring system, such as wrenches, sockets, drill bits, micrometers, rulers, and many others, come in both metric and imperial measurements. In many countries, metric measurements are the standard. However, conversion tables can be used to convert from one system to the other if needed.

Measuring Tape Measuring tapes are a flexible type of ruler and are a common measuring tool. The most common type found in shops is a thin metal strip about $\frac{1}{2}$ inch to 1 inch (13 to 25 mm) wide that is rolled up inside a housing with a spring return mechanism. Measuring tapes can be of various lengths, 16 to 25 feet (5 or 8 meters) and longer being very common. The measuring tape is pulled from the housing to measure items, and a spring return winds it back into the housing. The housing will usually have a built-in locking mechanism to hold the extended measuring tape against the spring return mechanism.

Stainless Steel Rulers As the name suggests, a stainless **steel ruler** is a ruler that is made from stainless steel. Stainless steel rulers commonly come in 12 inch, 24 inch, and 36 inch (30 cm, 61 cm, and 1 meter) lengths. They are used like any ruler to measure and mark out items. They are very strong, have precise markings, and resist damage. When using a stainless steel ruler, you can rest it on its edge so the markings are closer to the material being measured, which helps to mark the work precisely. Always protect the steel ruler from damage by storing it carefully; a damaged ruler will not give an accurate measurement. Never take measurements from the very end of a damaged steel ruler, as damaged ends may affect the accuracy of your measurements.

► TECHNICIAN TIP

Sometimes the end of your tape measure, or ruler, is damaged and you cannot reliably see the zero mark. If this is the case, simply start at the next whole number—for example, start at 1 inch or 1 cm. But don't forget to subtract that same number from the final measurement.

Outside, Inside, and Depth Micrometers Micrometers are precise measuring tools designed to measure small distances; they

are available in both millimeter (mm) and inch (") calibrations. Typically, they can measure down to a resolution of $\frac{1}{1,000}$ of an inch (0.001") for a standard micrometer or $\frac{1}{100}$ of a millimeter (0.01 mm) for a metric micrometer. Vernier micrometers equipped with the addition of a vernier scale can measure down to $\frac{1}{10,000}$ of an inch (0.0001 inch) or $\frac{1}{1,000}$ of a millimeter (0.001 mm). The most common types of micrometers are the outside, inside, and depth micrometers. As the name suggests, an **outside micrometer** (FIGURE 5-33A) measures the outside dimensions of an item. For example, it could measure the diameter of a valve stem. The **inside micrometer** measures inside dimensions. For example, the inside micrometer could measure an engine cylinder bore (FIGURE 5-33B). **Depth micrometers** measure the depth of an item, such as how far a piston is below the surface of the block (FIGURE 5-33C).

The most common micrometer is an outside micrometer. The horseshoe-shaped part is the frame. It is built to make sure the micrometer holds its shape. Some frames have plastic finger pads so that body heat is not transferred to the metal frame as easily, because heat can cause the metal to expand slightly and affect the reading. On one end of the frame is the anvil, which contacts one side of the part being measured. The other contact point is the spindle. The micrometer measures the distance between the anvil and spindle, so that is where the part being measured fits. The measurement is read on the sleeve/barrel and thimble. The sleeve/barrel is stationary and has linear markings on it. The thimble fits over the sleeve and has graduated markings on it. The thimble is connected directly to the spindle, and both turn as a unit. Because the spindle and sleeve/barrel have matching threads, the thimble rotates the spindle inside of the sleeve/barrel, and the thread moves the spindle inwards and outwards. The thimble usually incorporates either a ratchet or a clutch mechanism, which prevents overtightening of the micrometer thimble when taking a reading. A lock nut, lock ring, or lock screw is used on most micrometers and locks the thimble in place while you read the micrometer.

To read a standard micrometer, perform the following steps:

1. Verify that the micrometer is properly calibrated.
2. Verify what size of micrometer you are using. If it is a 0–1 inch micrometer, start with 0.000. If it is a 1–2 inch micrometer, start with 1.000 inch. A 2–3 inch micrometer would start with 2.000 inch, and so on. (To give an example, let's say it is 2.000".)
3. Read how many 0.100 inch marks the thimble has uncovered. (Example: 3×0.100 " marks = 0.300".)
4. Read how many 0.025 inch marks the thimble has uncovered past the 0.100 inch mark in step 3. (Example: 2×0.025 " marks = 0.050".)
5. Read the number on the thimble that lines up with the zero line on the sleeve. (Example: 13×0.001 " marks = 0.013".)
6. Lastly, total all the individual readings. (Example: 2.000 " + 0.300 " + 0.050 " + 0.013 " = 2.363".)

A metric micrometer uses the same components as the standard micrometer. However, it uses a different thread pitch

FIGURE 5-33 A. Outside micrometer. B. Inside micrometer. C. Depth micrometer.

on the spindle and sleeve. It uses a 0.5 mm thread pitch (2.0 threads per millimeter) and opens approximately 25 mm. Each rotation of the thimble moves the spindle 0.5 mm, and it therefore takes 50 rotations of the thimble to move the full 25 mm distance. The sleeve/barrel is labeled with individual millimeter marks and half-millimeter marks, from the starting millimeter to the ending millimeter, 25 mm away. The thimble has

graduated marks from 0 to 49. Reading a metric micrometer involves the following steps:

1. Read the number of full millimeters the thimble has passed. (To give an example, let's say it is 23 mm.)
2. Check to see if it passed the 0.5 mm mark. (Example: 0.50 mm.)
3. Check to see which mark the thimble lines up with or has just passed. (Example: $37 \times 0.01 \text{ mm} = 0.37 \text{ mm}$.)
4. Lastly, total all the numbers. (Example: $23 \text{ mm} + 0.50 \text{ mm} + 0.37 \text{ mm} = 23.87 \text{ mm}$.)

If the micrometer is equipped with a vernier gauge, meaning it can read down to $\frac{1}{1000}$ of a millimeter (0.001 mm), you need to complete one more step. Identify which of the vernier lines is closest to one of the lines on the thimble. Sometimes it is hard to determine which is the closest, so decide which three are the closest and then use the center line. At the frame side of the sleeve will be a number that corresponds to the vernier line. It will be numbered 1 to 0. Take the vernier number and add it to the end of your reading. For example: $23.77 + 0.007 = 23.777 \text{ mm}$.

For inside measurements, the inside micrometer works on the same principles as the outside micrometer, and so does the depth micrometer. The only difference is that the scale on the sleeve of the depth micrometer is backward, so be careful when reading it.

Using a Micrometer To maintain the accuracy of measurements, it is important that both the micrometer and the items to be measured are clean and free of any dirt or debris. Also, make sure the micrometer has been zeroed before taking any measurements. Never overtighten a micrometer or store it with its measuring surfaces touching, as this may damage the tool and affect its accuracy. When measuring, make sure the item can pass through the micrometer surfaces snugly and squarely. This is best accomplished by using the ratchet to tighten the micrometer. Always take the measurement several times and compare results to ensure you have measured accurately. To correctly measure using an outside micrometer, follow the guidelines in **SKILL DRILL 5-1**.

Telescoping Gauge For measuring distances in awkward spots, such as the bottom of a deep cylinder, the **telescoping gauge** has spring-loaded plungers that can be unlocked with a screw on the handle so that they slide out and touch the walls of the cylinder (**FIGURE 5-34**). The screw then locks them in that position, the gauge can be withdrawn, and the distance across the plungers can be measured with an outside micrometer or calipers to convey the diameter of the cylinder at that point. Telescoping gauges come in a variety of sizes to fit various sizes of holes and bores.

Split Ball Gauge A **split ball gauge (small hole gauge)** is good for measuring small holes where telescoping gauges cannot fit. They use a similar principle to the telescoping gauge, but the measuring head uses a split ball mechanism that allows it to fit into very small holes. Split ball gauges are ideal for measuring the wear on valve guides on a cylinder head.

SKILL DRILL 5-1 Precision Measurement Using an Outside Micrometer

1. Select the correct size of micrometer. Verify that the anvil and spindle are clean and that it is calibrated properly.
2. Clean the surface of the part you are measuring.
3. In your right hand, hold the frame of the micrometer between your little finger; ring finger; and palm of your hand, with the thimble between your thumb and forefinger.
4. With your left hand, hold the part you are measuring and place the micrometer over it.
5. Using your thumb and forefinger, lightly tighten the ratchet. It is important that the correct amount of force is applied to the spindle when taking a measurement. The spindle and anvil should just touch the component, with a slight amount of drag when the micrometer is removed from the measured piece. Be careful that the part is square in the micrometer so that the reading is correct. Try rocking the micrometer in all directions to make sure it is square.
6. Once the micrometer is properly snug, tighten the lock mechanism so that the spindle will not turn.
7. Read the micrometer and record your reading.
8. When all readings are finished, clean the micrometer; position the spindle so that it is backed off from the anvil and return it to its protective case.

FIGURE 5-34 Telescoping gauge.

A split ball gauge can be fitted in the bore and expanded until there is a slight drag. Then it can be retracted and measured with an outside micrometer. Like some of the other measuring instruments discussed, the split ball gauge may have a dial or digital measurement scale fitted for direct reading purposes.

Dial Bore Gauge A **dial bore gauge** is used to measure the inside diameter of bores, with a high degree of accuracy and speed (FIGURE 5-35). The dial bore gauge can measure a bore directly by using telescoping pistons on a T-handle with a dial mounted on the handle. The dial bore gauge combines a telescoping gauge and dial indicator in one instrument. A dial bore gauge determines whether the diameter is worn, tapered, or out-of-round according to the manufacturer's specifications. The resolution of a dial bore gauge is typically accurate to $\frac{5}{10,000}$ of an inch (0.0005") or $\frac{1}{100}$ of a millimeter (0.01 mm).

To use a dial bore gauge, select an appropriately sized adapter to fit the internal diameter of the bore, and install it to the measuring head. Many dial bore gauges also have a fixture to calibrate the tool to the size you desire. The fixture is set to the size desired, and the dial bore gauge is placed in it. The dial bore gauge is then adjusted to the proper reading. Once it is calibrated, the dial bore gauge can be inserted inside the bore to be measured. Hold the gauge in line with the bore and slightly rock it to ensure it is centered. Read the dial when it is fully centered and square to the bore to determine the correct measurement. Store a bore gauge carefully in its storage box, and ensure the locking mechanism is released while in storage. Bore gauges are

FIGURE 5-35 Dial bore gauge set.

available in different ranges of size. It is important to select a gauge with the correct range for the bore you are measuring. When measuring, make sure the gauge is at a 90-degree angle to the bore and read the dial. Always take the measurement several times and compare results to ensure you have measured accurately. To correctly measure using a dial bore gauge, follow the guidelines in **SKILL DRILL 5-2**.

Vernier Calipers Vernier calipers are a precision instrument used for measuring outside dimensions, inside dimensions, and depth measurements, all in one tool. They have a graduated bar with markings like a ruler. On the bar, a sliding sleeve with jaws is mounted for taking inside or outside measurements. Measurements on older versions of vernier calipers are taken by reading the graduated bar scales, while fractional measurements are read by comparing the scales between the sliding sleeve and

the graduated bar. Technicians will often use vernier calipers to measure the length and diameter of bolts and pins or the depth of blind holes in housings. Newer versions of vernier calipers have dial and digital scales. The dial vernier has the main scale on the graduated bar, while fractional measurements are taken from a dial with a rotating needle. These tend to be easier to read than the older versions. More recently, digital scales on vernier calipers have become commonplace. The principle of their use is the same as any vernier caliper; however, they have a digital scale that reads the measurement directly.

Always store vernier calipers in a storage box to protect them and ensure that the measuring surfaces are kept clean for accurate measurement. If making an internal or external measurement, make sure the caliper is at right angles to the surfaces to be measured. You should always repeat the measurement several times and compare results to ensure you have measured accurately. To correctly measure using vernier calipers, follow the guidelines in **SKILL DRILL 5-3**.

Dial Indicators Dial indicators can also be known as dial gauges, and as the name suggests, they have a dial and needle where measurements are read. They have a measuring plunger with a pointed contact end that is spring-loaded and connected via the housing to the dial needle. The dial accurately measures movement of the plunger in and out as it rests against an object. For example, they can be used to measure the trueness of a rotating disc brake rotor. A dial indicator can also measure how round something is. A crankshaft can be rotated in a set of V blocks. If the crankshaft is bent, it will show as movement on the dial indicator as the crankshaft is rotated. The dial indicator senses slight movement at its tip and magnifies it into a measurable swing on the dial. Dial indicators typically measure ranges from 0.010 inch to 12 inches or 0.25 mm to

SKILL DRILL 5-2 Precision Measurement Using a Dial Bore Gauge

1. Select the correct size of the dial bore gauge you will use and fit any adapters to it.
2. Check the calibration and adjust it as necessary.
3. Insert the dial bore gauge into the bore. The accurate measurement will be at exactly 90 degrees to the bore. To find the accurate measurement, rock the dial bore gauge handle slightly back and forth until you find the centered position.
4. Read the dial to determine the bore measurement.
5. Always clean the dial bore gauge and return it to its protective case when you have finished using it.

SKILL DRILL 5-3 Precision Measurement Using Vernier Calipers

- 1.** Verify that the vernier caliper is calibrated (zeroed) before using it. If it has not been zeroed, notify your mentor, who will get you a replacement vernier caliper.
- 2.** Position the caliper correctly for the measurement you are making. Internal and external readings are normally made with the vernier caliper positioned at 90 degrees to the face of the component to be measured. Length and depth measurements are usually made parallel to or in line with the object being measured. Use your thumb to press or withdraw the sliding jaw to measure the outside or inside of the part.
- 3.** Read the scale of the vernier caliper, being careful not to change the position of the movable jaw. Always read the dial or face straight on. A view from the side can give a considerable parallax error. A parallax error is a visual error caused by viewing measurement markers at an incorrect angle.

300 mm and have graduation marks of 0.0005 inch to 0.01 inch or 0.001 mm to 0.01 mm. The large needle can move numerous times around the outer scale. One full turn may represent 1 mm or 0.1 inch. The small inner scale indicates how many times the outer needle has moved around its scale. In this way, the dial indicator can read movement of up to 1 inch or 2.54 cm. Dial indicators can measure with an accuracy of 0.001 inch or 0.01 mm. The type of dial indicator you use will be determined by the amount of movement you expect from the component you are measuring. The indicator must be set up such that there is no gap between the dial indicator and the component to be measured. Most dial indicator sets contain various attachments and support arms so that they can be configured specifically for the measuring task.

Dial indicators are used in many types of service jobs. They are particularly useful in determining runout on rotating shafts and surfaces. Runout is the side-to-side variation of movement when a component is turned. When attaching a dial indicator, keep support arms as short as possible. Make sure all attachments are tightened to prevent unnecessary movement between the indicator and the component. Make sure the dial indicator pointer is positioned at 90 degrees to the face of the component to be measured. Always read the dial face straight on, as a view from the side can give a considerable parallax error. The outer face of the dial indicator is designed so that it can be rotated in such a way that the zero mark can be positioned directly over the pointer. This is how a dial indicator is zeroed. To correctly measure using a dial indicator, follow the guidelines in **SKILL DRILL 5-4**.

Straight Edge **Straight edges** are usually made from hardened steel and are machined so that the edge is perfectly straight. A straight edge is used to check the flatness of a surface.

It is placed on its edge against the surface to be checked. The gap between the straight edge and the surface can be measured by using feeler gauges. Sometimes the gap can be seen easily if light is shone from behind the surface being checked. Straight edges are often used to measure the amount of warpage the surface of a cylinder head has.

Feeler Gauges **Feeler gauges** (also called *feeler blades*) are used to measure the width of gaps, such as the clearance between valves and rocker arms. Feeler gauges are flat metal strips of varying thicknesses. The thickness of each feeler gauge is clearly marked on each one. They are sized from fractions of a millimeter or fractions of an inch. They usually come in sets with different sizes and are available in metric and imperial measurements. Some sets contain feeler gauges made of brass. These are used to take measurements between magnetic components. If steel gauges were used, the drag caused by the magnetism would mimic the drag of a proper clearance. Brass gauges are not subject to magnetism, so they work well in that situation. Some feeler gauges come in a bent arrangement to be more easily inserted in cramped spaces. Others come in a stepped version. Two or more feeler gauges can be stacked together to make up a desired thickness. Alternatively, if you want to measure an unknown gap, you can interchange feeler gauges until you find the one (or more) that fits snugly into the gap, then total their thickness to measure the gap. In conjunction with a straight edge, they can be used to measure surface irregularities in a cylinder head.

If the feeler gauge feels too loose when measuring a gap, select the next larger size and measure the gap again. Repeat this procedure until the feeler gauge has a slight drag between both parts. If the feeler gauge is too tight, select a smaller size

SKILL DRILL 5-4 Precision Measurement Using a Dial Indicator

- 1.** Select the gauge type, size, attachment, and bracket that fit the part you are measuring. Mount the dial indicator firmly to keep it stationary.
- 2.** Adjust the indicator so that the plunger is at 90 degrees to the part you are measuring and lock it in place.
- 3.** Rotate the part one complete turn and locate the low spot. Zero the indicator.
- 4.** Find the point of maximum height and note the reading. This will indicate the runout value.
- 5.** Continue the rotation and make sure the needle does not go below zero. If it does, reverse the indicator and re-measure the point of maximum variation.
- 6.** Check your readings against the manufacturer's specifications. If the deviation is greater than the specifications allow, consult your supervisor.

SKILL DRILL 5-5 Selecting and Using Feeler Gauge Sets

- 1.** Select the appropriate type and size of feeler gauge set for the job you are working on.
- 2.** Inspect the feeler gauges to make sure they are clean, rust-free, and undamaged, but slightly oiled for ease of movement.
- 3.** Choose one of the smaller wires or blades and try to insert it in the gap on the part. If it slips in and out easily, choose the next size up. When you find one that touches both sides of the gap and slides with only gentle pressure, then you have found the exact width of that gap.
- 4.** Read the markings on the wire or blade and check these against the manufacturer's specifications for this component. If gap width is outside the tolerances specified, inform your supervisor.
- 5.** Clean the feeler gauge set with an oily cloth to prevent rust when you store the set.

until the feeler gauge fits properly. When measuring a spark plug gap, feeler gauges should not be used, because the surfaces are not perfectly parallel, so it is preferable to use **wire feeler**

gauges. Wire feeler gauges use accurately machined pieces of wire instead of metal strips. To select and use feeler gauge sets, follow the guidelines in **SKILL DRILL 5-5.**

Air-Operated Tools

As a technician, you will use **air tools** often. Air tools will make up an expensive and indispensable part of a technician's personal tools. As such, it is important to know their proper selection, usage, and care. Air tools, or pneumatic-operated tools, typically run at 120 psi (5.74 kPa), so exercise caution around them. Compressed air is transported through pipes and hoses. Air tools have quick-connect fittings so that various air tools can easily be used on the same air hose. Although there are several styles of quick-connect fittings, a shop usually uses one style throughout the entire shop. An **air ratchet** uses the force of compressed air to turn a ratchet drive (**FIGURE 5-36A**). It is used on smaller nuts and bolts. Once the nut has been loosened, the air ratchet spins it off in a small fraction of the time it would take by hand. The air ratchet also works well when there is not much room to swing a ratchet handle.

An **air nozzle** is probably the simplest air tool (**FIGURE 5-36B**). It simply controls the flow of compressed air. It is controlled by a lever or valve and is used to blast debris and dirt out of confined spaces. Blasting debris and dirt can be dangerous, so eye protection must be worn whenever this tool is used. Noise levels are usually high, so ear protection should also be worn. It is dangerous to use an air nozzle to clean yourself off. Its blast should always be directed away from the user and anyone else working nearby.

An **air hammer**, sometimes called an *air chisel*, is useful for driving and cutting (**FIGURE 5-36C**). The extra force that is generated by the compressed air makes it more efficient than a hand chisel and hammer. Just as there are many chisels, there are many bits that fit into the air hammer. Selecting which one to use depends on the job at hand.

An **air drill** has some important advantages over the more common electric power drill (**FIGURE 5-36D**). With the right attachment, an air drill can drill holes, grind, polish, and clean parts. Unlike the electric drill, it does not carry the risk of producing sparks, which is an important consideration around flammable liquids or petroleum tanks. An air drill does not trail a live electric lead behind it that could be cut and possibly cause

shock and burns. Neither does it become hot with heavy use. The most common air tool in a repair shop is the **air-impact wrench** (**FIGURE 5-36E**). It is also called an *impact gun* or *rattle gun*, and it is easy to understand why when you hear one. Taking the wheels off a vehicle to replace the tires is a typical application for this air tool. Removing lug nuts often requires a lot of torque to twist the nuts free, and air-impact wrenches work well for that. The air-impact wrench may be set to spin in either direction, and a valve controls roughly how much torque it applies. It should never be used for the final tightening of wheel nuts. There is a danger in overtightening the wheel nuts, as this could cause the bolts to fail and the wheel to separate from the vehicle while it is moving. Another rule to remember about the air-impact wrench is that you must use special hardened impact sockets, extensions, and joints. The sockets are special heavy-duty, six-point types, and the flats can withstand the hammering force that the impact wrench subjects them to. Air can also be used to power a **grease gun**, which is used to lubricate components with grease fittings. The air power forces the grease through the aperture.

It is critical for the MORE technician to be a subject matter expert on all different types of tools; including hand tools, air tools, precision measuring tools, and many other types of tools. You should be an expert on the proper selection, application and usage, and maintenance of tools. Having expert tool knowledge will save you an enormous amount of time, money, frustration, and possible equipment damage and injuries over your career. Follow **SKILL DRILL 5-6** to learn some techniques for the proper selection, usage, and maintenance of tools.

► Purpose, Usage, and Types of Fasteners

K05002

Locking devices or fasteners used in this industry are primarily designed to hold things in a particular location or to hold things together. These devices come in many forms, and depending on the particular application, one or more types of locking devices may be used. They can be in the form of a physical fastener or chemical adhesive. This chapter provides a description of the types of locking devices and fasteners found in MORE design equipment applications.

Types of Fasteners

There are many different fasteners used in equipment applications, including screws, bolts, studs, and nuts. Washers and chemical compounds can be used to help secure these fasteners.

Screws

Screws are generally smaller than bolts and are sometimes referred to as metal threads (**FIGURE 5-37**). They can have a variety of heads, they're used on smaller components, and their thread often extends right from the tip to the head so that they can hold together components of different thickness.

FIGURE 5-36 A. Air ratchet. B. Air nozzle. C. Air hammer. D. Air drill. E. Air-impact wrench.

SKILL DRILL 5-6 Steps for the Proper Selection, Use, and Maintenance of Tools

It is important to select, use, and maintain the proper tools when completing a job. Here are some basic tips and step-by-step procedures for ensuring your tools serve you well.

- Keep your personal tools organized and maintain an up-to-date inventory of your tools. A great way to accomplish this is to use foam inserts in your tool box drawers cut to the exact shape of each tool. This way you can easily know where the proper location for each tool is and when a tool is missing.
- Ensure you maintain your tools and any tools that have broken are separated from your working tools so that they can be repaired or replaced.
- Don't loan out tools to people you don't trust, but if you do, have them fill out a hand receipt to establish accountability for the tool.

3. Determine whether you have all the other tools to accomplish this job and that they are in proper working order.

6. Then return all tools to their proper location.

Try these steps to see how well you can select and use the proper tools for a job. On your next repair job, do the following:

1. Before starting a job, look up the repair procedure in the manufacturer's technical information; pay attention to special tools referenced and what other tools you think you may need to accomplish the repair.

4. Perform the repair job per the equipment manufacturer's instructions.

7. Evaluate the following:

- How much time did it take to properly check out and return tools?
- Did you have to go back and retrieve tools that you had not anticipated a need for before starting the repair? How much added time did this take?
- If you checked out any special shop tools, were they in proper working order and maintained when you got them?
- Did you, or your shop, not have some tools that you needed?
- Looking back on the repair, were there any tools you could have used that would have saved time or made the repair job safer?

It is important over time that you improve and learn more effective techniques in the selection, use, and maintenance of tools. Don't be the person who is struggling for hours to complete a repair when if you had the correct tool, you could accomplish in minutes.

2. Determine whether your shop has the needed special tools (if any), and determine whether they are in proper working order and have been maintained.

5. After the repair is completed, determine whether any tools require repair or maintenance.

FIGURE 5-37 Screws are generally smaller than bolts and are sometimes referred to as metal threads.

FIGURE 5-39 A machine screw.

FIGURE 5-38 **A.** An Allen head screw and **B.** an Allen wrench set.

Different screws can be tightened with a range of tools. An **Allen head screw** has a recess for an **Allen wrench** (**FIGURE 5-38**). An Allen head screw is sometimes called a hex head screw. It usually screws into a hole rather than a nut, and it needs to be tightened with an Allen wrench.

A **machine screw** has a slot for a screwdriver (**FIGURE 5-39**). Screwdrivers come in many sizes, and you should always use the correct size of blade for the machine screw slot. There are several special screws that cut their own threads as they go. This is called *tapping a thread*. Pictured in **FIGURE 5-40A** is a **self-tapping screw**. It is made of hard material that cuts a

FIGURE 5-40 Self-tapping screws.

FIGURE 5-41 Bolt nomenclature.

FIGURE 5-42 Standard thread shapes.

mirror image of itself into the hole as you turn it. The screw in **FIGURE 5-40B** is also known as a self-tapping screw, but it is designed for cutting and holding thin sheet metal, so it is often used on car bodies.

Bolts, Studs, and Nuts

Bolts, studs, and nuts are fasteners designed for heavier jobs than screws and tend to be made of metal or metal alloys. **Bolts** are cylindrical pieces of metal with a hexagonal head on one end and a thread cut into the shaft at the other end (**FIGURE 5-41**). They are often bigger than screws and are used for heavier jobs. Bolts are always threaded into a nut or hole that has an identical thread cut inside. The thread acts as an inclined plane; as the bolt is turned, it is drawn into or out of the matching thread.

► TECHNICIAN TIP

Threads are cut on screws, bolts, nuts, and studs and inside holes to allow components to be attached and assembled. There was a time when there were many different thread designs used throughout the world. Modern equipment still use a range of thread patterns, but due to standardization, it is getting much simpler (**FIGURE 5-42**). Nearly all the nuts, bolts, screws, and studs on a vehicle have a V-thread cut into them. A screw jack or a clamp has square threads cut into it. The square thread is more difficult to machine and is used mainly when rotational movement needs to be transferred into lateral movement—for example, the screw in a vice where the rotary movement of turning the handle is translated into the lateral movement of the jaws closing.

Nuts are often used with bolts. A nut is a piece of metal, usually hexagonal, with a thread cut through it to fit the bolt thread. The hexagonal heads for the bolt and nut are designed to fit tools such as combination wrenches and sockets (**FIGURE 5-43**).

Torx drivers are used for **torx screws**, which enable more tightening torque to be applied to a screw than a similar-sized hex head screw would without damaging the head. Because they better resist coming out, they are often found in engines or places with limited space and a compact screw head is required (**FIGURE 5-44**).

FIGURE 5-43 Bolts usually have hexagonally shaped heads.

FIGURE 5-44 Torx screws are often found in places such as cylinder heads to engine blocks, where high-tightening torque is required and there is limited space for a larger fastener.

FIGURE 5-45 A self-locking nut is highly resistant to being loosened by engine vibrations.

There are many ways to keep the nut and bolt done up tightly. A self-locking or **nyloc nut** can have a plastic or nylon insert. Tightening the bolt squeezes it into the insert, where it resists any movement. The self-locker is highly resistant to being loosened by vibration between parts (**FIGURE 5-45**). Tightening this style of nut distorts the insert, so it provides its locking effect only the first time you use it. If you remove the nut, it should be replaced with a new one.

A **castellated nut** has slots like towers on a castle (**FIGURE 5-46**). When it is screwed onto a bolt that has been drilled in the right spot, a split pin can be passed through them both and then spread open to lock the nut in place. Castellated nuts are a very secure type of fastener used when safety is critical. They are also used when scheduled maintenance requires inspection and adjustments to take place for items such as front wheel bearings.

A **speed nut** is not as strong as the other types, but it can be a fast and convenient way to secure a screw (**FIGURE 5-47**). Once the speed nut has been started, it does not need to be held.

FIGURE 5-46 A castellated nut.

FIGURE 5-47 Speed nut.

These are often used in places like body component fixings. Some bolts and nuts need washers. Washers can be made from several materials depending on their application, including aluminum, copper, fiber, and steel.

Here are some brief descriptions of the more common washers:

- **Flat washers** spread the load of a bolt head or a nut as it is tightened and distribute it over a greater area (**FIGURE 5-48A**). This protects the surface underneath from being marked by the nut or head as it turns and tightens down. Flat washers should always be used to protect aluminum alloy.
- A **spring (lock) washer** compresses as the nut tightens, and the nut is spring-loaded against this surface, which makes it unlikely to work loose (**FIGURE 5-48B**). The ends of the spring washer also bite into the metal. Spring washers are used more for bolts and nuts.
- Screws mostly rely on smaller **serrated-edge shake-proof washers** (**FIGURE 5-48C**). The external ones have teeth on the outside, and the internal ones have teeth on the inside; one type has both.

FIGURE 5-48 Types of washers: **A.** Flat washer. **B.** Spring washer. **C.** Serrated edge shake-proof washers. **D.** Spindle washer.

- **Spindle washers** are used behind a wheel bearing. The key or tab on the washer (**FIGURE 5-48D**) prevents the washer from spinning due to bearing rotation.

Often, the thread on a stud is only as long as it needs to be to tighten onto the nut or into the threaded hole. Some special

FIGURE 5-49 A stud has threads on both ends.

versions have both a left- and right-hand thread on them. A **stud** (**FIGURE 5-49**) is like two bolts in one; for instance, an exhaust manifold on the cylinder head is normally located and held by studs and nuts. A stud does not have a fixed hexagonal head; rather, it is one continuously threaded piece. When a stud is used, it is threaded into one part, where it stays. The mating part is then slipped over it and a nut is threaded onto the end of the stud to secure the part. Studs are commonly used to attach an axle shaft flange to the hub, and they can have different threads on each end. Bolts, nuts, and studs can have either standard or metric threads. They are designated by their thread diameter, thread pitch, length, and grade. The diameter is measured across the outside of the threads; it is measured in fractions of an inch for standard-type fasteners and millimeters for metric-type fasteners. A $\frac{3}{8}$ inch (9.5 mm) bolt has a thread diameter of $\frac{3}{8}$ inch (9.5 mm); $\frac{3}{8}$ inch (9.5 mm) is not the size of the bolt head.

The **standard (imperial) system** also uses a marking system to indicate tensile strength, as shown in **FIGURE 5-50**. This is a grade 5 bolt, which can be tightened to specific torque as specified by the manufacturer. **Torque** is a way of defining how much a fastener should be tightened.

The metric, or SI, system uses numbers stamped on the heads of metric bolts and on the face of metric nuts (**FIGURE 5-51**). Even

FIGURE 5-50 Tensile strength markings using the standard system—a grade 5 bolt.

FIGURE 5-51 Bolts and nuts are often marked to indicate how much torque can be safely applied to them. Markings using the metric system are shown here.

studs have a marking system to make sure they are not overstressed when you tighten them.

The numbers indicate the *tensile strength* of the bolt. The number does *not* mean the size of the bolt. *Note:* The distance between flats on the bolt or nut heads generally indicates the wrench size to be used. The number of threads along the length of a fastener is called **thread pitch** (**FIGURE 5-52A**). In the standard system, the thread pitch is measured in threads per inch (tpi), which is the distance between the peaks of the threads in inches (**FIGURE 5-52B**). Each bolt diameter in the metric system can have up to four thread pitches. Metric threads, designated with a capital M, are rated according to their outer diameter and their pitch (**FIGURE 5-52C**).

► TECHNICIAN TIP

The global version of metric is called the International System of Units, or SI. The standard system of inch-pounds is still used by some manufacturers, particularly in the United States. The metric system, however,

FIGURE 5-52 **A.** The terms when describing a thread are marked in this illustration. **B.** In the standard system, pitch is measured in threads per inch (tpi). **C.** In the metric system, the thread pitch is measured by the distance between the peaks of the threads in millimeters.

has produced some competing classifications for fasteners. For example, metric hex cap screws may have three different standards:

1. DIN 931 (DIN 933 fully threaded)
2. ISO 4014 (ISO 4017 fully threaded)
3. ANSI/ASME B18.2.3.1M.

These three standards are interchangeable, differing primarily in the width across the flat dimensions.

The length of a bolt is fairly straightforward. It is measured from the end of the bolt to the bottom of the head and is listed in inches or millimeters. The grade of a fastener relates to its strength. The higher the grade number, the higher the **tensile strength**, which refers to how much tension it can withstand before it breaks. Tensile strength for fasteners is generally listed in pounds per square inch (psi) or megapascals (MPa) of bolt shaft area.

► TECHNICIAN TIP

Many bolts and nuts need to be tightened to a specified level—tight enough to hold components together but not so tight that the com-

ponent or the fastener could fail. This force applied to a fastener used to tighten it is called the **torque specification**. Bolts and nuts are often marked with grades to indicate their strength, which determines how much torque can safely be applied to them. For example, a grade 8 bolt is stronger than a grade 5 bolt and can be tightened to a higher torque. The specific torque required for every bolt on the vehicle should always be obtained from the manufacturer's technical information system. Once bolts are tightened, there are different ways to ensure they stay tight. For example, a locking washer, a locking chemical compound, or a nylon locking device built into the nut may be used.

Fasteners and Torque

Fasteners are designed to secure parts that are under various tension and shear stresses. The nature of the stresses placed on parts and fasteners depends on their use and location. For example, head bolts withstand *tension stresses* by clamping the head gasket between the cylinder head and the block. The bolts must withstand the very high combustion pressures trying to push the head off the engine block in order to leak past the head gasket. An example of fasteners withstanding *shear stresses* is wheel studs and wheel nuts. They clamp the wheel assembly to the suspension system, and the weight of the vehicle tries to shear the lug studs. If this were to happen, the wheel

would fall off the vehicle, leading to an accident. To accomplish their job, fasteners come in a variety of diameters and levels of hardness, which are defined in tensile strength grades. Fasteners with screw threads are designed to be tightened to a specific torque depending on the job at hand, the tensile strength or hardness of the material they are made from, their size, and the thread pitch. If a fastener is overtightened, it could become damaged or could break. If it is under-tightened, it could work loose over time.

Torque Charts

Torque specifications for bolts and nuts in vehicles will usually be contained within shop manuals. Bolt, nut, and stud manufacturers also produce torque charts, which contain all the information you need to determine the maximum torque of bolts or nuts (**FIGURE 5-53**). For example, most charts include the bolt diameter, threads per inch (mm), grade, and maximum torque setting for both dry and lubricated bolts and nuts (**TABLE 5-1**). A lubricated bolt and nut will reach maximum torque value at a lower setting. In practice, most torque specifications call for the nuts and bolts to have dry threads prior to tightening. There are some exceptions, so closely examining the torque specification chart is critical.

In the absence of torque specifications the values below can be used as a guide to the maximum safe torque for a specific diameter/grade of fastener. The torque specification is for clean dry threads, if the threads are oiled reduce the torque by 10%.

Bolt Diameter	Bolt Grade Marking									
										
	Maximum Torque		Maximum Torque		Maximum Torque		Maximum Torque		Maximum Torque	
	lb ft	Nm	lb ft	Nm	lb ft	Nm	lb ft	Nm	lb ft	Nm
M4	0.8	1.1	1	1.5	2	3	3	4.5	4	5
M5	1.5	2.5	2	3	4.5	6	6.5	9	7.5	10
M6	3	4	4	5.5	7.5	10	1.1	15	13	18
M8	7	9.5	10	13	18	25	26	35	33	45
M10	14	19	18	25	37	50	55	75	63	85
M12	26	35	33	45	63	85	97	130	111	150
M14	37	50	55	75	103	140	151	205	177	240

1"	12	710	860	990

Torque Wrenches

A **torque wrench** is also known as a tension wrench (**FIGURE 5-54**).

It is used to tighten fasteners to a predetermined torque. It is designed to tighten bolts and nuts using the drive on the end, which fits with any socket and accessory of the same drive size found in an ordinary socket set. Although manufacturers do

not specify torque settings for every nut and bolt, it is important to follow the specifications when they do. For example, manufacturers recommend a specific torque for cylinder head bolts. The torque specified will ensure that the bolt provides the proper clamping pressure and will not come loose, but will not be so tight as to risk breaking the bolt or stripping the threads (**FIGURE 5-55**).

FIGURE 5-54 The torque wrench has an adjustable handle, which allows technicians to adjust to the correct tightening torque specification for the job.

FIGURE 5-55 The torque wrench is fitted over the wheel locking nuts and tightened to the specified torque.

The torque value will be specified in foot-pounds (ft-lb) or newton meters (N·m). The torque value is the amount of twisting force applied to a fastener by the torque wrench. For example, foot-pound (newton meter) is described as the amount of twisting force applied to a shaft by a perpendicular lever 1 foot (meter) long with a force of 1 pound (newton) applied to the outer end. A torque value of 100 ft-lb will be the same as applying a 100-pound force to the end of a 1-foot-long lever. (*One ft-lb is equal to 1.35 N·m.*) Torque wrenches come in various types: beam-style, clicker, dial, and electronic (**FIGURE 5-56**).

The simplest and least expensive is the *beam-style* torque wrench. It uses a spring steel beam that flexes under tension. A smaller fixed rod then indicates the amount of torque on a scale mounted to the bar. The amount of deflection of the bar coincides with the amount of torque on the scale. One drawback of this design is that you must be positioned directly above the scale so you can read it accurately. That can be a problem when working in a confined space. The *clicker-style* torque wrench uses an adjustable clutch inside that slips (clicks) when the preset torque is reached. You can set it for a particular torque on the handle. As the bolt is tightened, once the preset torque is reached, the torque wrench will click. This makes it especially useful in situations where the scale of a beam-style torque wrench cannot be read. The higher the torque, the louder the click; the lower the torque, the quieter the click. Be careful when using this style of torque wrench, especially at lower torque settings. It is easy to miss the click and then over-tighten, break, or strip the bolt. Once the torque wrench clicks, stop turning it, as it will continue to tighten the fastener if you turn it past the click point. The *dial* torque wrench turns a dial that indicates the torque based on the torque being applied. Like the beam-style torque wrench, you must be able to see the dial to know how much torque is being applied. Many dial torque wrenches have a movable indicator that is moved by the dial and stays at the highest reading. That way, you can double-check the torque achieved once the torque wrench is released. Once the proper torque is reached, the indicator can be moved back to zero for the next fastener being torqued.

FIGURE 5-56 Torque wrench.

The *digital* torque wrench usually uses a spring steel bar with an electronic strain gauge to measure the amount of torque being applied. The torque wrench can be preset to the desired torque. It will then display the torque as the fastener is being tightened. When it reaches the preset torque, it will usually give an audible signal, such as a beep. This makes it useful in situations where a scale or dial cannot be read. Torque wrenches fall out of calibration over time or if they are not used properly, so they should be checked and calibrated annually. This can be performed in the shop if the proper calibration equipment is available, or the torque wrench can be sent to a qualified service center.

Most quality torque wrench manufacturers provide a recalibration service for their customers.

To help ensure that the proper amount of torque gets from the torque wrench to the bolt, support the head of the torque wrench with one hand (**FIGURE 5-57**).

When using a torque wrench, it is best not to use extensions. Extensions twist and deflect when used, which reduces the actual amount of torque applied to a fastener. If possible, use a deep socket rather than adding an extension. Torque is not always the best method of ensuring that a bolt is tightened enough to give the proper amount of clamping force. If the threads are rusty, rough, or damaged in any way, the amount of twisting force required to overcome thread friction increases. Tightening a rusty fastener to a particular torque will not provide as much clamping force as a smooth fastener torqued the same amount. All threads must be clean before tightening the fastener to a specified torque. This also brings up the question of whether threads should be lubricated. In most cases, the torque values specified are for dry, non-lubricated threads, but always check the manufacturer's specifications. When bolts are tightened, they are also stretched. If they are not tightened too much, they will return to their original length when loosened. This is called **elasticity**. If they continue to be tightened and stretch beyond their point of elasticity, they will not return to their original length when

FIGURE 5-57 Ensure the proper amount of torque gets from the torque wrench to the bolt by supporting the head of the torque wrench with one hand.

loosened. This is called the **yield point**. **Torque-to-yield (TTY)** means that a fastener is torqued to, or just beyond, its yield point. With the changes in engine metallurgy that manufacturers are using in modern vehicles, bolt technology has had to change as well. To help prevent bolts from loosening over time and to maintain an adequate clamping force when the engine is both cold and hot, manufacturers have adopted “stretch” or (TTY) bolts.

TTY bolts are designed to provide a consistent clamping force when tightened to their yield point or just beyond. It is important to note that in virtually all cases, TTY bolts cannot be reused, because they have been stretched into their yield zone and would very likely fail if re-torqued. Always check the manufacturer’s specifications when doing this because some manufacturers say that the bolt must be changed once a maximum length has been reached. Another tightening procedure is the **torque angle** method. Torque angle is considered a more precise method to tighten bolts and is a multistep process (**FIGURE 5-59**). Bolts are first tightened to a specific torque, and then an additional number of turns, degrees of rotation, or flat rotation are made (**FIGURE 5-58**).

To use a torque wrench and torque angle gauge, follow the guidelines in **SKILL DRILL 5-7**.

SAFETY TIP

For your safety,

- refer to the manufacturer’s specifications when tightening fasteners
- return the torque wrench to its lowest setting when finished
- if replacing a fastener, make sure it has the correct tensile value for the task it will perform.

FIGURE 5-58 Torque sequence.

FIGURE 5-59 Angle gauge.

SKILL DRILL 5-7 Using a Torque Wrench and Torque Angle Gauge

1. Clean and install a bolt. Lightly tighten the bolt with a hand ratchet.
2. Check the specifications. Determine the correct torque value and sequence for the bolts or fastener you are using. This will be in foot-pounds (ft-lb) or newton meters (N·m). Also, check the torque angle specifications for the bolt or fastener and whether the procedure requires only one step or more than one step.
3. Tighten the bolt to the specified torque. If the component requires multiple bolts or fasteners, make sure to tighten them all

to the same torque value in the sequence and follow the steps specified by the manufacturer. Some torquing procedures could call for four or more steps to complete the torquing process. For example, vehicle specifications as follows:

- a. Step 1: Torque bolts to 30 foot-pounds (40 newton meters).
- b. Step 2: Torque bolts to 44 foot-pounds (60 newton meters)
- c. Step 3: Finally, tighten the bolt a further 90 degrees.

► Wrap-Up

To become a successful MORE technician you must become an expert in tools, fasteners, and measuring equipment. Know how to select the proper tool for the job, how to use it, and how to maintain your tools. Your personal tools will likely become one of your largest financial investments, so take good care of them.

Ready for Review

- ▶ Tools and equipment should be used only for the task they were designed to do.
- ▶ Always have a safe attitude when using tools and equipment and wear necessary personal protection equipment.
- ▶ Do not use damaged tools; inspect them before using, then clean and inspect again before putting them away.
- ▶ Fasteners will use external markings to designate their grade and type of thread.
- ▶ Micrometers can be outside, inside, or depth.
- ▶ Gauges are used to measure distances and diameters; types include telescoping, split ball, and dial bore.
- ▶ Dial indicators are used to measure movement.
- ▶ A straight edge is designed to assess the flatness of a surface.
- ▶ Feeler blades are flat metal strips that are used to measure the width of gaps.
- ▶ Air tools use compressed, pressurized air for power; types include the air-impact wrench, air ratchet, air hammer, air drill, and blowgun/air nozzle.
- ▶ Sockets grip fasteners tightly on all six corners. Sockets are classified as follows: standard or metric, size of drive used to turn them, number of points, depth of socket, and thickness of wall.
- ▶ Threaded fasteners include bolts, studs, and nuts and are designed to secure vehicle parts under stress.
- ▶ Torque defines how much a fastener should be tightened.
- ▶ Flat washers spread the load on a bolt or nut.
- ▶ Metric bolts are sized and classified by millimeters in diameter and the distance in millimeters between the thread peaks.
- ▶ Imperial system bolts are sized and classified by the diameter and the number of threads per inch.
- ▶ Torque wrenches and torque angle gauges are used to ensure the bolts torque.
- ▶ TTY bolts are usually not reusable, because they stretch when they are tightened correctly.

Key Terms

air drill A compressed-air-powered drill.

air hammer A tool powered by compressed air with various hammer, cutting, punching, or chisel attachments. It's also called an air chisel.

air-impact wrench An impact tool powered by compressed air designed to undo tight fasteners. It's also called a rattle gun, or impact gun.

air nozzle A compressed-air device that emits a fine stream of compressed air for drying or cleaning parts.

air ratchet A ratchet tool for use with sockets powered by compressed air.

air tools A tool that is powered by compressed air, also called pneumatic tools.

Allen head screw Sometimes called a hex head screw, it has a hexagonal recess in the head that fits an Allen key. This type of screw usually anchors components in a predrilled hole.

Allen wrench A type of hexagonal drive mechanism for fasteners.

aviation snips A scissor-like tool for cutting sheet metal.

ball-peen (engineer's) hammer A hammer that has a head that is rounded on one end and flat on the other, which is designed to work with metal items.

bench vice A device that securely holds material in jaws while it is being worked on.

blind rivet A rivet that can be installed from its insertion side.

bolt A type of threaded fastener with a thread on one end and a hexagonal head on the other.

bolt cutters Strong cutters available in different sizes, designed to cut through non-hardened bolts and other small-stock material.

bottoming tap A thread-cutting tap designed to cut threads to the bottom of a blind hole.

C-clamp A clamp shaped like the letter C; it comes in various sizes and can clamp various items.

castellated nut A nut with slots, similar to towers on a castle, that is used with split pins; it is used primarily to secure wheel bearings.

closed end A wrench with a closed or ring end to grip bolts and nuts.

club hammer The club hammer is like a small mallet, with two square faces made of high-carbon steel. It is the heaviest type of hammer that can be used one-handed.

combination pliers A type of pliers for cutting, gripping, and bending.

combination wrench A type of wrench that has an open end on one end and a closed-end wrench on the other.

crescent wrench The open-ended adjustable wrench, or crescent wrench, which has an adjustable thumb wheel that moves the lower jaw to grip smaller or larger fasteners.

cross-cut chisel A type of chisel for metal work that cleans out or cuts key ways.

curved file A type of file that has a curved surface for filing holes.

dead-blow hammer A type of hammer that has a cushioned head to reduce the amount of head bounce.

depth micrometers A micrometer that measures the depth of an item such as how far a piston is below the surface of the block.

diagonal-cutting pliers Pliers for small wire or cable.

dial bore gauge A gauge that is used to measure the inside diameter of bores with a high degree of accuracy and speed.

dial indicators A dial that can also be known as a dial gauge, and as the name suggests, it has a dial and needle where measurements are read.

die stock handle A handle for securely holding dies to cut threads.

double flare A seal that is made at the end of metal tubing or pipe.

drift punch A type of punch used to start pushing roll pins to prevent them from spreading.

drill vice A tool with jaws that can be attached to a drill press table for holding material that is to be drilled.

elasticity The amount of stretch or give a material has.

fasteners Devices that securely hold items together, such as screws, cotter pins, rivets, and bolts.

feeler gauges Flat metal strips used to measure the width of gaps, such as the clearance between valves and rocker arms; also called feeler blades.

finished rivet A rivet after the completion of the riveting process.

flare-nut wrench A type of closed-end wrench that has a slot in the box section to allow the wrench to slip through a tube or pipe. It's also called a flare-tubing wrench.

flat-nosed pliers Pliers that are flat and square at the end of the nose.

flat tip screwdriver A type of screwdriver that fits a straight slot in screws.

flat washers Spread the load of bolt heads or nuts as they are tightened and distribute it over a greater area. They are particularly useful in protecting aluminum alloy.

gasket scraper A broad, sharp, flat blade to assist in removing gaskets and glue.

gear pullers A tool with two or more legs and a cross-bar with a center forcing screw to remove gears.

grease gun A device used to force grease into an item, usually a grease fitting. It can be powered by hand, compressed air, or electricity.

impact driver A tool that is struck with a blow to provide an impact turning force to remove tight fasteners.

inside micrometer A micrometer that measures inside dimensions.

intermediate tap One of a series of taps designed to cut an internal thread; also called a plug tap.

locking pliers A type of plier where the jaws can be set and locked into position.

machine screw A screw with a slot for screwdrivers.

magnetic pickup tools An extending shaft, often flexible, with a magnet fitted to the end for picking up metal objects.

mandrel The shaft of a pop rivet.

mechanical fingers Spring-loaded fingers at the end of a flexible shaft that pick up items in tight spaces.

mechanic's mirror A small mirror on a stick that can be adjusted to view leaks, identify tags, and find dropped parts and tools. It can be placed into areas that are difficult to view or access.

mobile off-road equipment (MORE) Mobile equipment designed specifically for off-highway use. Examples are front-end loaders, back-hoes, haul trucks, trenchers, mining equipment, etc.

needle-nosed pliers Pliers with long tapered jaws for gripping small items and getting into tight spaces.

nippers Pliers designed to cut protruding items level with the surface.

nut A fastener with a hexagonal head and internal threads for screwing on bolts.

nyloc nut Keeps the nut and bolt done up tightly; it can have a plastic or nylon insert. Tightening the bolt squeezes it into the insert, where it resists any movement. The self-locker is highly resistant to being loosened.

offset screwdriver A screwdriver with a 90-degree bend in the shaft for working in tight spaces.

offset vice A vice that allows long objects to be gripped vertically.

oil-filter wrench A wrench used to grip and loosen an oil filter. Not to be used for tightening an oil filter.

open-ended adjustable wrench The open-ended adjustable wrench, or crescent wrench, has an adjustable thumb wheel that moves the lower jaw to grip smaller or larger fasteners.

open-end wrench A wrench with open jaws to allow side entry to a nut or bolt.

outside micrometer A micrometer that measures the outside dimensions of an item.

peening A term used to describe the action of flattening a rivet through a hammering action.

personal protective equipment (PPE) Safety equipment designed to protect the technician, such as safety boots, gloves, clothing, protective eyewear, and hearing protection.

Phillips screwdriver A type of screwdriver that fits a head shaped like a cross in screws. It's also called a Phillips head screwdriver.

pin punch A type of punch in various sizes with a straight or parallel shaft.

pliers A hand tool with gripping jaws.

pop-rivet gun A hand tool for installing pop rivets.

press fit An interference fit, also called a press fit or friction fit, is a means of fastening two parts together so that they are in direct contact with one another and are held in place only by friction, or the tightness of the fit. There is negative clearance between the interference fit parts, so they must be pressed or forced together.

prick punch A punch with a sharp point for accurately marking a point on metal.

pry bars A high-strength carbon-steel rod with offsets for levering and prying.

pullers A generic term to describe hand tools that mechanically assist the removal of bearings, gears, pulleys, and other parts.

punches A generic term to describe a high-strength carbon-steel shaft with a blunt point for driving. Center and prick punches are exceptions and have a sharp point for marking or making an indentation.

ratchet A generic term to describe a handle for sockets that allows the user to select the direction of rotation. It can turn sockets in restricted areas without the user having to remove the socket from the fastener.

ratcheting closed-end wrench A closed-end wrench that has a ratcheting mechanism so that the tool does not have to be removed, to continue turning.

ratcheting open-end wrench An open-end wrench that can be moved slightly and then repositioned so that the tool does not have to be completely removed in order to continue turning it.

ratcheting screw driver A screwdriver with a selectable ratchet mechanism built into the handle that allows the screwdriver tip to ratchet as it is being used.

safe working load (SWL) The maximum safe lifting load for lifting equipment.

screws Usually smaller than bolts and are sometimes referred to as metal threads. They can have a variety of heads and are used on smaller components. The thread often extends from the tip to the head so they can hold together components of variable thickness.

screw extractor A tool for removing broken screws or bolts.

self-tapping screw A screw that cuts down its own thread as it goes. It is made of hard material that cuts a mirror image of itself into the hole as you turn it.

serrated-edge shake-proof washer A washer that is used to anchor smaller screws.

single flare A sealing system made on the end of metal tubing.

sliding T-handle A handle fitted at 90 degrees to the main body that can be slid from side to side.

snap ring pliers A pair of pliers for installing and removing internal or external snap rings.

socket An enclosed metal tube commonly with 6 or 12 points to remove and install bolts and nuts.

soft-face steel hammers A type of hammer featuring a drop forged head specifically designed to mushroom when striking hard base materials are gaining popularity for added safety against chipping and spalling causing injury.

speed brace A U-shaped socket wrench that allows high-speed operation. It's also called a speeder handle.

speed nut A nut usually made of thin metal; it does not need to be held when started, but it is not as strong as a conventional nut. It's a fast and convenient way to secure a screw.

split ball gauge (small hole gauge) A gauge that is good for measuring small holes where telescoping gauges cannot fit.

spring washer A washer that compresses as the nut tightens; the nut is spring-loaded against this surface, which makes it unlikely that it will work loose. The ends of the spring washer also bite into the metal.

square file A type of file with a square cross-section.

square thread A thread type with square shoulders used to translate rotational to lateral movement.

standard (imperial) Bolts, nuts, and studs can have either metric or imperial threads. They are designated by their thread diameter, thread pitch, length, and grade. Imperial measures are in feet, inches, and fractions of inches. Most countries use metric.

steel ruler A ruler that is made from stainless steel. Stainless steel rulers commonly come in 30 mm, 60 mm, and 1 meter lengths.

straight edges A measuring device generally made of steel to check how flat a surface is.

stud A type of threaded fastener with a thread cut on each end, as opposed to having a bolt head on one end.

tab washer A washer that gets its name from the small tabs that are folded back to secure the washer. After the nut or bolt has been tightened, the washer remains exposed and is folded up to grip the flats and prevent movement.

tap A term used to generically describe an internal thread-cutting tool.

tap handle A tool designed to securely hold taps for cutting internal threads.

taper tap A tap with a taper; it is usually the first of three taps used when cutting internal threads.

telescoping A gauge used for measuring distances in awkward spots, such as the bottom of a deep cylinder.

tensile strength The amount of force required before a material deforms or breaks.

thread chaser A device similar to a die that cleans up rusty or damaged threads.

thread pitch The coarseness or fineness of a thread as measured by the distance from the peak of one thread to the next, in threads per inch.

thread repair A generic term to describe a number of processes that can be used to repair threads.

tin snips A cutting device for sheet metal, which works in a similar fashion to scissors.

tool A physical item used to do something or accomplish a goal.

torque The twisting force applied to a shaft that may or may not result in motion.

torque angle A method of tightening bolts or nuts based on angles of rotation.

torque specification Describes the amount of twisting force allowable for a fastener or a specification showing the twisting force from an engine crankshaft, which is supplied by manufacturers.

torque-to-yield (TTY) A method of tightening bolts close to their yield point or the point at which they will not return to their original length.

torque-to-yield (TTY) bolts Bolts that are tightened using the torque-to-yield method.

torque wrench A tool used to measure the rotational or twisting force applied to fasteners.

torx bolt A type of screw with an internal or external six point star shaped head.

tube-flaring tool A tool that makes a sealing flare on the end of metal tubing.

universal joint A flexible joint that goes between two rotating shafts, allowing them to operate at different angles to one another.

vehicle hoist A type of vehicle lifting tool designed to lift the entire vehicle.

vernier caliper An accurate measuring device for internal, external, and depth measurements that incorporates fixed and adjustable jaws.

yield point The point at which a bolt is stretched so hard that it fails; it is measured in pounds per square inch (psi) or kilopascals (kPa) of bolt cross-section.

wad punch A type of punch, which is hollow, used for cutting circular shapes in soft materials, such as gaskets.

warding file A type of thin, flat file with a tapered end.

slip joint pliers Adjustable pliers with parallel jaws that allow you to increase or decrease the size of the jaws by selecting a different set of channels.

welding helmet Protective gear designed for arc welding; it provides protection against foreign articles entering the eye, and the lens is tinted to reduce the glare of the welding arc.

wrench A generic term to describe tools that tighten and loosen fasteners with hexagonal heads.

Review Questions

- Torque values are measured in _____ meters.
 - mega
 - kilo
 - pound
 - newton
- Which of the following are among the many different fasteners used in heavy-duty equipment applications.
 - Screws
 - Bolts
 - Nuts
 - All of the above
- _____ strength refers to the amount of force a bolt can take before it fails.
 - Shaft
 - Thread
 - Tensile
 - Turning
- Manufacturer's charts showing _____ will assist in identifying standard and metric sizing.
 - thread zoning
 - Fastener sizing
 - Both A and B
 - Neither A nor B

- The _____ micrometer measures parts that are placed in between the anvil and spindle.
 - inside
 - outside
 - depth
 - standard
- _____ pliers, also called vice grips, are general purpose pliers used to clamp and hold one or more objects.
 - Arc joint
 - Locking
 - Needle-nosed
 - Flat-nosed

ASE Technician A/Technician B Style Questions

- Technician A says that you would use an outside micrometer to measure the inside diameter of the bottom of a cylinder. Technician B says that you would use a dial bore gauge to measure the bottom diameter of a cylinder for out of round. Who is correct?
 - Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
- Technician A says bolt cutters cut hardened rods. Technician B says tin snips can cut thin sheet metal. Who is correct?
 - Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
- Technician A says if a fastener is overtightened, it could become damaged or could break. Technician B says if a fastener is under-tightened, it is likely to be satisfactory for reuse. Who is correct?
 - Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
- Technician A says torque specifications for bolts and nuts in vehicles will usually be contained within workshop manuals. Technician B says that in practice, most torque specifications call for the nuts and bolts to have oiled threads prior to tightening. Who is correct?
 - Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
- Technician A says one of the tools used to repair damaged bolt holes is the helical insert, more commonly known by its trademark, Heli-Coil. Technician B says Heli-Coils are made of coiled wire and are inserted into a tapped hole that is larger than the desired hole. Who is correct?
 - Technician A
 - Technician B
 - Both A and B
 - Neither A nor B

6. Technician A says the most commonly used pair of pliers in the shop is the needle-nosed plier. Technician B says the most common is the snap ring plier. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
7. Technician A says that a drift punch is also named a starter punch because you should always use it first to get a pin moving. Technician B says a center punch centers a drill bit at the point where a hole is required to be drilled. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
8. Technician A states that a tap handle has a right-angled jaw that matches the squared end that all taps have. Technician B states that to cut a thread in an awkward space, a T-shaped tap handle is very convenient. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
9. Technician A says that you should use a depth gauge to measure the thrust end play in a shaft. Technician B says that you should use a dial bore gauge. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
10. Technician A says that a Torx head fastener is shaped like a star. Technician B says that an Allen (hex) head fastener is shaped like a star? Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B

CHAPTER 6

Oxyacetylene-Heating and Cutting Equipment

Knowledge Objectives

After reading this chapter, you will be able to:

- **K06001** Describe oxyacetylene equipment and components.
- **K06002** Explain safety regulations for heating, cutting, and welding of metals.
- **K06003** Describe oxyacetylene-heating, cutting, and welding processes.
- **K06004** Describe brazing and soldering processes.
- **K06005** Recommend correct repair techniques for welding metal using oxyacetylene equipment.

Industry/Accreditation

After reading this chapter, you will be able to:

- **I06001** Communicate trade-related information using standard terms for oxyacetylene-heating and cutting procedures.

Skills Objectives

After reading this chapter, you will be able to:

- **S06001** Demonstrate the proper procedures for cutting, welding, soldering, and brazing of metals.

Attitude Objectives

After reading this chapter, you will be able to:

- **A06001** Locate and follow appropriate safety procedures when heating, cutting, and welding metal.

► Introduction

The use of oxyacetylene equipment for heating, cutting, welding, brazing, and soldering metal is a common practice in many heavy equipment repair shops and industrial settings. Oxyacetylene cutting and welding is based on combining acetylene, which is a highly combustible gas, with oxygen to produce very high flame temperatures that are needed for metal working. Since oxyacetylene equipment does not require electricity and is commonly available in portable outfits, mobile off-road equipment (MORE) service technicians can take it onsite and use it for tasks such as heating and loosening rusted fasteners, cutting pieces of metal, and joining or patching metals. This chapter identifies and describes oxyacetylene equipment and explains safety regulations associated with using the equipment. It also describes heating, cutting, welding, brazing, and soldering processes performed with oxyacetylene equipment and examines some repair techniques that can be used for welding.

► Oxyacetylene Equipment and Components

K06001

A typical oxyacetylene outfit consists of numerous major (standard) components, along with other supplemental components that enable technicians to operate the equipment safely and use the equipment for specific jobs.

Standard Equipment

The major components that make up a typical oxyacetylene outfit include an acetylene cylinder, an oxygen cylinder, a pressure regulator for each cylinder, a **flashback arrestor** on the outlet of each regulator, a hose for each gas, a **check valve** (or a second flashback arrestor) at the end of each hose, and a torch (**FIGURE 6-1**). Many oxyacetylene outfits used in the field are portable—that is, the cylinders and other components are placed on some type of wheeled cart that enables the equipment to be moved safely and easily.

The two cylinders hold the oxygen and acetylene gases under pressure. Each cylinder has a screw-on protective cap that should remain in place when the cylinders are not in use. Removing the protective caps reveals a valve on top of each cylinder that can be opened to allow the gas to flow from the cylinder and closed to shut off the gas flow (**FIGURE 6-2**).

FIGURE 6-1 Typical oxyacetylene equipment.

FIGURE 6-2 Protective caps and cylinder valves.

Attached to each cylinder is a pressure regulator that has two pressure gauges (**FIGURE 6-3**). One gauge is called the **cylinder pressure gauge**. It shows how much pressure is in the cylinder. The other gauge is called the **working pressure gauge**. It shows how much pressure is in the hose, or line. The line pressure for each gas can be adjusted using an adjusting screw on the applicable pressure regulator.

Located between the outlet of the pressure regulators and the hoses that lead to the torch handle are flashback arrestors. Flashback arrestors are spring-loaded valves that prevent

You Are the Mobile Heavy Equipment Technician

You are called to a construction site to service a customer's dozer. While you are there, you notice a crack in a frame support underneath the dozer that requires removal before a replacement can be attached. Your service truck is equipped with a portable oxyacetylene cutting torch, so you know you'll be able to make the repair. But you have some questions.

1. Where might you find information about the proper gas pressure settings to use when cutting?
2. Is there a way to identify the proper size and type of cutting torch tip to use?
3. What safety precautions should you use when cutting off the frame member?

FIGURE 6-3 Pressure regulators and gauges.

FIGURE 6-5 Twin-line oxyacetylene hose.

FIGURE 6-4 Flashback arrestors.

backflow from the torch handle and hoses (FIGURE 6-4). More specifically, they prevent a flame from traveling back up the hose to the cylinders in the case of a **flashback**, which occurs when the oxygen and acetylene burn inside the torch handle. During a flashback, the gas flame enters into nozzle or torch and is accompanied by a loud popping sound or hiss. The flame will either extinguish or re-ignite at the nozzle. Flashback happens if the torch valve pressures are set lower than they should be for a particular tip, which produces low gas flow out of the tip. Flashback can also happen if cylinder pressures are too low, or if the torch tip becomes over heated such as when it is held too close to the work.

► TECHNICIAN TIP

The use and locations of flashback arrestors and check valves on oxyacetylene equipment can vary. Flashback arrestors are positioned between the regulators and the hoses, and check valves are positioned between the hoses and the torch handle. Both flashback arrestors and check valves can be positioned between the regulators and the hoses. In an ideal situation, flashback arrestors are positioned between the regulators and the hoses and between the hoses and the torch handle. While both devices allow flow through the hoses in one direction only—from

the cylinders to the torch handle—only a flashback arrestor can prevent a detonation wave caused by a flame inside the torch handle from traveling back up the hose and into the acetylene cylinder. It should also be noted that some torch handles have built-in flashback arrestors and check valves, making it unnecessary to use separate flashback arrestors and check valves at the torch handle.

The hoses run from the flashback arrestors at the regulators to check valves (or a second set of flashback arrestors) on the torch handle. Different sizes and colors are used for the hoses, but a common convention is red for the acetylene hose and green for the oxygen hose (FIGURE 6-5). The oxygen and acetylene hoses are typically connected together for most of their length to form what is called **twin-line hose**.

► TECHNICIAN TIP

Red and green hoses are typical for oxyacetylene equipment. However, a combination of red hoses is used for acetylene, and blue or black hoses are used for oxygen. To prevent gas connections from inadvertently becoming interchanged, acetylene gas connections use left-hand threads, while oxygen use right-hand threads. This means connections turn in two different directions for each gas when either tightening or loosening fittings. Left-hand threads will typically use a notch mark on the thread fittings.

The torch handle (or torch body) is the part of the equipment that the technician holds and moves about during operation. The torch handle usually has check valves or flashback arrestors screwed into it where the hoses connect. Gas flow control valves that can be used to adjust the flow of oxygen and acetylene are at the base of the handle. The top of the handle is threaded so that different tips and attachments can be installed for heating, cutting, and welding (FIGURE 6-6).

Tips and attachments provide an area for the oxygen and acetylene to mix and form a flame at the end of the tip. The tips and attachments used on the torch handle can vary a great deal, depending on the type of work to be done and the type and thickness of the metal being worked on. Torch tip manufacturers provide sizing charts that identify the

FIGURE 6-6 Torch handle.

FIGURE 6-8 Torch with cutting attachment and cutting tip.

FIGURE 6-7 Torch with rosebud heating tip.

proper tip to use for various metal thicknesses. Such charts also specify the pressures to use for the oxygen and acetylene. Technicians should always follow the tip manufacturers' guidelines when selecting the appropriate tip for the work being performed.

As a general rule, welding tips and special heating tips called **rosebud** tips and **MFA** tips are used for heating metal (FIGURE 6-7). Heating tips have numerous holes in the end that produce multiple flames with a wide pattern suitable for heating metal. The flame is directed toward the area of the metal that must be heated. Once the metal is cherry red, it can be bent or otherwise manipulated. As with all tips, heating tips come in various sizes. Technicians should always use the heating tip recommended by the manufacturer.

Cutting metal typically requires a cutting attachment and a cutting tip (FIGURE 6-8). A typical cutting attachment has three pipes running to the nozzle—one pipe for oxygen, one pipe for acetylene, and one pipe for oxygen from the oxygen blast lever. When this type of torch is used, the metal to be cut is first heated by an oxyacetylene flame. Once the metal begins to melt, the oxygen blast lever is pressed to provide a high-pressure stream of oxygen to cut through the metal.

FIGURE 6-9 Torch with welding tip.

► TECHNICIAN TIP

When cutting metal that is greater than 8 inches (203 mm) thick, a dedicated cutting torch must be used instead of a torch handle with a cutting attachment and cutting tip. A cutting torch has the same oxygen and acetylene connections and valves as a typical torch handle, and it has an oxygen blast lever. It is simply built as a single torch that can be used in heavy duty operations.

A torch with a welding tip is used for welding metals (FIGURE 6-9). Unlike a cutting torch, a welding torch has no oxygen blast lever. A welding torch may not have any visible pipes running to the nozzle, or it may have only two pipes—one for oxygen and one for acetylene. As with a typical torch handle, a welding torch has gas flow control valves that enable a technician to adjust the flow of oxygen and acetylene.

► TECHNICIAN TIP

While a welding torch is designed to weld metal, it can also be used to heat small objects like fasteners that have rusted or seized up. This eliminates the need to change from a welding tip to a heating tip for a small job.

Supplemental Components

Excluding personal protection and safety equipment, there are numerous additional components and tools that are typically used with oxyacetylene equipment. For example, one or more wrenches are needed for loosening and tightening tip, torch, hose, regulator, and cylinder connections on oxyacetylene equipment (**FIGURE 6-10**). The cylinder valves are usually opened with knobs although smaller acetylene cylinders may be opened with a T-wrench. Other connector sizes can vary with the equipment. **FIGURES 6-10A** and **B** show typical oxyacetylene system connections.

A striker is a tool used to light the torch (**FIGURE 6-11**). When the two arms of a striker are squeezed together, the ends of the arms brush against a piece of flint and create sparks that ignite the oxyacetylene fuel. Most strikers use replaceable flints that can be purchased separately.

Tip cleaners are used routinely to remove buildup from cutting and welding tips that block or interfere with gas flow (**FIGURE 6-12**). A common tip cleaner tool has an array of round steel files, or **reamers**, to fit different tip orifice sizes. Most tip cleaner tools include a flat file that can be used to remove buildup on the outside of the tip. Using tip cleaners on a regular basis helps extend the life of the tip and maintain the proper flame pattern.

When oxyacetylene equipment is used to weld, braze, or solder two pieces of metal together, some type of filler metal

must be used during the process (**FIGURE 6-13**). The specific filler metal that is used will depend on the metal being joined. Filler metal often comes in the form of filler rods. Gas welding rods range in size from $\frac{1}{16}$ -inch (1.6 mm) diameter to $\frac{1}{4}$ -inch (6.4 mm) diameter, with most rods being 36 inches (914 mm) in

FIGURE 6-11 A striker.

FIGURE 6-12 Torch tip cleaner tool.

FIGURE 6-10 **A.** Oxygen bottle connections. **B.** Acetylene bottle connections.

FIGURE 6-13 Common filler materials.

length. Common welding rods used for filler material are available as carbon steel, aluminum, and various alloys, including bronze and copper. Filler metals used for brazing and soldering commonly include bronze, silver solder and other alloys.

► Safety Regulations

K06002

Safety must be the first and foremost priority when working with oxyacetylene equipment. Cylinder pressures and flame temperatures alone pose significant hazards. The pressure inside a full cylinder of acetylene is approximately 250 psi (1,724 kPa), while the pressure in an oxygen cylinder is approximately 2,200 psi (15,168 kPa). When acetylene is mixed with oxygen, very high flame temperatures of 6,300°F to 6,800°F (3,480°C to 3,760°C) are produced. To ensure that they protect themselves and other personnel, technicians must follow safety rules related to clothing and protective gear, the work area environment, and the manner in which they use oxyacetylene equipment.

Personal Protective Equipment

Technicians should always wear appropriate personal protective equipment (PPE) when heating, cutting, or welding with oxyacetylene equipment (**FIGURE 6-14**). The exact protective equipment that is needed can vary according to regulations and company standards, the activity being performed, and the work environment.

As a general rule, the following PPE should be worn during oxyacetylene heating, cutting, and welding:

- A solid material (non-mesh) hat made of flame-retardant material. The bill of the hat should be facing to the rear.
- Tight-fitting welding goggles with the proper light-reducing shade for the work being done. The **American National Standards Institute (ANSI)** publishes a shade range guide for various types of welding and cutting activities in its *ANSI Z49.1* standard. A typical shade range for

FIGURE 6-14 Typical personal protective equipment.

oxyacetylene work is from shade 3 to shade 6, but some heavy welding activities require a shade 8.

SAFETY TIP

Sunglasses should not be worn as a substitute for welding goggles because they do not filter the extreme ultraviolet light as effectively. In addition, the plastic used in the lenses of sunglasses will not protect your eyes from sparks.

- A face shield over the welding goggles to protect the face from flying sparks, debris, and heat.
- Earmuffs (or earplugs) to minimize noise and protect ear canals from sparks.

SAFETY TIP

In some applications, such as cutting or welding material overhead, a full leather hood with a properly tinted face plate is preferable to wearing separate welding goggles and a face shield. In addition, if a hard hat is required in the work area, the hard hat must be able to accommodate the face-shield and rear deflector attachments.

- A protective leather apron or, at a minimum, flame-retardant clothing capable of protecting against ultraviolet light and hot sparks. Shirts should have long sleeves; pants should have no cuffs; and jackets should have no pockets, where hot metal can collect.
- Long leather welding gloves to protect hands and arms.
- Leather work boots. The tongue and lace area of each boot should be tall enough to be covered by the pants legs. Otherwise, leather **spats** should be used to cover the front of the boots.

While working around the flames and high heat associated with oxyacetylene heating, cutting, and welding, technicians should not wear jewelry or body-piercing studs. These items can snag on equipment and absorb heat from the torch flame.

Breathing masks or respirators may be required when heating, cutting, or welding certain materials. For example, copper, lead, mercury, zinc, and other materials can produce toxic fumes when heated with a torch. For short-term exposure to some fumes, a technician may be safe using a high-efficiency particulate arresting (HEPA) filter or a metal-fume filter (**FIGURE 6-15**). But if a technician is exposed to such toxic fumes for a long period of time, a full-face supplied-air respirator (SAR) is necessary.

SAFETY TIP

Using oxyacetylene equipment to cut metal containing zinc, such as galvanized steel, may be prohibited in some locations because of the toxic nature of the fumes that are released in the process. Always verify whether flame cutting of galvanized steel is permitted, and if so, be sure to wear the appropriate breathing equipment.

FIGURE 6-15 Worker wearing a respirator.

Work Area Safety

Whenever oxyacetylene equipment is used, there is an inherent risk of fire and explosion. To minimize these and other risks, technicians should always inspect and prepare the machinery or equipment to be worked on, as well as the work area and its surroundings before using oxyacetylene equipment. Maintaining a safe work area typically includes the following:

- Remove flammable materials such as rags, paper, boxes, and flammable liquids from the work area or shield them using a fire-resistant cover. Many work site fires are caused by cutting torches, so maintaining a neat and clean work area can greatly reduce accidental fires.
- Make sure that approved fire extinguishers are readily accessible before starting any heating, cutting, or welding operation.
- Make sure that oxyacetylene equipment is properly positioned at the work site to avoid trip hazards.
- Determine if the work area is a **confined space** or if it requires a hot-work permit or a fire watch. If so, follow all requirements and procedures for the site. Many sites require hot-work permits and fire watches, and failure to abide by these requirements can lead to serious injuries and penalties.
- Make sure that the work area is properly ventilated. This is especially true for confined spaces. Fans, exhaust hoods, and ventilated booths can all be used to provide the necessary ventilation.
- Do not use oxygen to ventilate a work area. Releasing a large amount of oxygen into the work space can cause rapid and uncontrolled combustion if a spark ignites flammable material. Oxygen should be kept away from petroleum products to prevent fire and explosions.
- Never release acetylene into a work area. Acetylene is lighter than air, and if it's mixed with air or oxygen, it can explode at lower concentrations than other fuels.

Safe Equipment Use and Storage

Technicians must follow appropriate safety guidelines when operating and storing oxyacetylene equipment.

Safe Equipment Use

Safe equipment use typically includes the following:

- Never use acetylene at a pressure above 15 psig (103 kPa).
- Turn regulator adjustment screws counterclockwise until they are free before opening cylinder valves. When opening cylinder valves, stand to the side of the regulators.
- Always use an appropriate striker to light the oxyacetylene torch. Never carry matches or gas-filled cigarette lighters or attempt to use them to light the torch. Using matches or lighters requires technicians to position their hand(s) too close to the torch tip. Plus, sparks can ignite matches and cause lighters to explode.
- Use caution when handling a lighted torch. Never point the torch flame toward a person or any flammable material in the area.
- If possible, place a heat shield behind the workpiece being heated, cut, or welded to protect other objects in the area from becoming hot. Also, use chalk or soapstone to write "HOT" on any hot metal to protect other personnel from touching it.
- Before heating, cutting, or welding any kind of tank, barrel, or pipe, make sure the container did not previously contain explosive, hazardous, or flammable materials. Always clean containers and fill them with water or purge them with an inert gas to prevent fire, explosion, or toxic fumes.
- While working, avoid breathing in cutting or welding fumes and smoke. Use a fan, if necessary, to divert the fumes and smoke. Wear an appropriate breathing apparatus to avoid toxic fumes when necessary.
- Never use oxygen to blow dust and dirt off clothing or equipment. Oxygen can remain trapped in clothing and ignite and burn rapidly if exposed to a spark.
- Ensure that all scrap metal or **dross** being discarded has cooled to a point where it does not pose a fire hazard.

Safe Equipment Storage

To minimize fire and explosion hazards, it is critical to follow safety guidelines related to the storage of oxyacetylene equipment that is not in use. Safe equipment storage rules include the following:

- Oxygen cylinders and acetylene cylinders must be stored separately (**FIGURE 6-16**). The cylinders must be kept at least 20 feet (6 meters) apart or separated by a wall that is 5 feet (1.5 meters) high with a minimum 30-minute burn rating. These safeguards are intended to prevent any small fire in the area from causing an oxygen cylinder safety valve to open and fuel an uncontrolled blaze.
- Cylinder storage areas must be located away from exits, halls, and stairwells to avoid blocking escape routes during an emergency. Cylinders should also be located where unauthorized personnel cannot tamper with them and in areas where they will not be affected by heat, radiators, furnaces, and welding sparks. Appropriate warning signs must be posted in the storage area.

FIGURE 6-16 Cylinder storage area.

- Empty cylinders should be stored separately from full cylinders. They can, however, be stored in the same room or area.
- All cylinders must be stored vertically, and their protective caps should be screwed on firmly.
- Because the cylinders store gases at high pressure, they must be secured with a chain or other device to prevent them from being knocked over accidentally. If an oxygen cylinder falls over and the main valve breaks, high-pressure gas inside the cylinder will enable it to become a missile with enough force to penetrate concrete block walls.

► Oxyacetylene Heating, Cutting, and Welding

K06003

The processes used to heat, cut, and weld metal using oxyacetylene equipment can involve connecting the components, setting up the equipment so that it can be operated safely and effectively, testing connections for leaks, adjusting the gas valves and regulators to the correct flows and pressures, lighting and adjusting the torch flame, and following the equipment manufacturer's recommendations for performing the appropriate task.

Initial Equipment Setup

If technicians are required to set up oxyacetylene equipment for use, they must follow all the applicable safety precautions, wear the appropriate PPE, and use the equipment manufacturer's guidelines for setup. Most of the initial steps for preparing oxyacetylene equipment to use for heating, cutting, and welding metal are basically the same. While there can be subtle differences in the equipment being used, most oxyacetylene equipment requires the following basic setup steps.

1. Carefully position the cart that is holding the oxygen and acetylene cylinders so that they are close enough for the hoses to reach the work but far enough away to avoid sparks, flames, and intense heat. Both cylinders must be upright and properly secured in the cart with a chain.

2. Before making any connections, clear the cylinder valves on both cylinders. First, remove the protective cap from the acetylene cylinder and place it where it will not be lost. Standing with the cylinder's outlet nozzle pointing away, use a T-wrench or other appropriate tool to briefly crack open the cylinder valve about a one-quarter turn counterclockwise. After a second or two, turn the valve clockwise to close it. Use a clean cloth to wipe out the inside of the valve nozzle to remove any remaining dirt or debris. Repeat the procedure for the oxygen cylinder to ensure that all debris has been cleared.
3. Attach the regulators to the cylinders. Turn the adjusting screw on the acetylene cylinder's valve outlet nozzle counterclockwise until no resistance can be felt. Place the regulator fitting inside the valve nozzle and use a wrench to tighten the regulator nut. Follow the same steps to attach the oxygen regulator to the oxygen cylinder valve. Remember that oxygen and acetylene fittings use right- and left-hand threads, respectively. Never use any oil to lubricate threads since high-pressure oxygen will ignite any oil and grease on the threads.
4. Install a flashback arrestor in each regulator outlet. Follow the equipment manufacturer's recommendations regarding the type and placement of flashback arrestors.
5. Connect the hoses to the flashback arrestors. The red hose should attach to the flashback arrestor on the acetylene regulator, and the green hose should attach to the flashback arrestor on the oxygen regulator. The acetylene hose has a notched fitting, which indicates it is a left-hand thread that must be turned counterclockwise to tighten. The oxygen fitting should be turned clockwise.

► TECHNICIAN TIP

New oxyacetylene hoses may have a powder lining the interior. If that is the case, the hoses should first be blown out before connecting. Hold the loose ends of the hoses so that they point away, open the acetylene cylinder valve, and turn the adjusting screw of the acetylene regulator clockwise until the working pressure gauge reads 10 psig (69 kPa). Allow the acetylene to flow out for two seconds, and then close the adjusting screw and the cylinder valve. Repeat the procedure for the oxygen hose.

6. Install a check valve or flashback arrestor between the end of each hose and the torch handle to prevent reverse gas flow (backflow). Make sure that the red acetylene hose is connected to the acetylene check valve and that the green oxygen hose is connected to the oxygen check valve.
7. Identify the proper torch handle for the job and attach it to the check valves on the hose ends. Make sure all connections follow the red and green color coding for hoses. Acetylene hoses and connections are all left-hand threads, while oxygen gas connections are right-hand threads. This means that the acetylene connections are made counterclockwise and the oxygen connections are made clockwise. All connections must be tightened using an appropriate wrench. Check for leaks with soapy water sprayed over all connections after gas pressure is supplied to the hoses.

8. Select the proper type of tip for the work being done. Check the condition of the tip and, if necessary, use a tip cleaning tool to clean the tip before use. Screw the tip onto the torch end and tighten it. The torch tip fitting allows the gas valves on the torch handle to be aligned for a comfortable, easily accessible working position.
9. Test all equipment connections for leaks with soapy water and check for gas leaks by observing whether bubbles appear on connections under gas pressure. Correct any leakage before proceeding further. To do this, first, close the oxygen and acetylene torch valves. Then, turn both valves clockwise to open them. Standing to one side, slowly open the oxygen cylinder valve about a half turn. Turn the adjusting screw for oxygen regulator until the working pressure gauge reads 20 psig (138 kPa). Then open the acetylene cylinder valve a quarter turn, and turn the acetylene regulator adjusting screw until the working pressure gauge reads 5 psig (35 kPa). Close both cylinder valves and watch the cylinder pressure gauges. If there is a drop in pressure on the gauges, there must be a leak. Retighten all the connection fittings and repeat the test. If a leak is still indicated, brush all the fittings and hoses with a **leak test solution** and watch for bubbles to appear at the leak site. If a leak cannot be corrected, replace the fitting, component, or hose as needed.

Heating

Using oxyacetylene equipment to heat metal requires the use of a heating tip that is appropriate for the metal being worked on. Rosebuds and MFA (multiple flame acetylene) tips are used in many heating applications, but technicians should always use the torch tips recommended by the equipment manufacturer. Technicians should also wear the proper PPE when preparing the equipment and heating metal.

The basic process for heating metal using oxyacetylene equipment is as follows:

1. Determine the type and thickness of the metal to be heated.
2. Follow the manufacturer's recommended heating tip size to select the proper tip for the job.
3. Inspect the heating tip for damage or plugged flame holes. Clean the tip with a tip cleaner if necessary.
4. Install and tighten the heating tip according to the manufacturer's instructions.
5. Close the oxygen and acetylene flow control valves on the torch handle.
6. Loosen (back out) the adjusting screws on the oxygen and acetylene regulators.
7. Stand to the side of the oxygen cylinder and slowly open the cylinder valve until the proper pressure is indicated on the regulator working pressure gauge. High gas pressure suddenly released from the cylinder can damage regulator components. Once the pressure on the cylinder pressure gauge rises, open the oxygen cylinder valve all the way. Opening the valve all the way backseats the valve to prevent oxygen leakage past the valve stem.
8. Stand to the side of the acetylene cylinder and slowly open the cylinder valve until the cylinder pressure gauge on the

regulator displays the cylinder pressure. Do not open the acetylene cylinder valve more than one and a half turns. This enables the gas to be quickly shut off in the event of an emergency.

9. Open the oxygen flow control valve on the torch handle completely.
10. While the oxygen is flowing, tighten the adjusting screw on the oxygen regulator until the proper working pressure is displayed. Continue the oxygen flow for 10 seconds to purge the hoses and torch.
11. Close the oxygen flow control valve on the torch handle.
12. Open the acetylene flow control valve on the torch handle approximately one-eighth of a turn.
13. While the acetylene is flowing, tighten the adjusting screw on the acetylene regulator until the proper working pressure is displayed. Continue the acetylene flow for 10 seconds to purge the hoses and torch.
14. Close the acetylene flow control valve on the torch handle.

SAFETY TIP

Never let the acetylene working pressure rise above 15 psig (103 kPa). At pressures above 15 psig (103 kPa), acetylene can become unstable and explode.

15. Open the acetylene flow control valve on the torch handle approximately one-quarter of a turn.
16. Use a friction lighter to ignite the torch.
17. Use the acetylene flow control valve to increase the acetylene flow until the flame leaves the end of the heating tip and stops smoking. Then, decrease the acetylene flow until the flame returns to the tip.
18. Slowly open the oxygen flow control valve until a **neutral flame** is achieved. A neutral flame is characterized by one or more inner cones, which are light blue in color, surrounded by a darker blue outer flame envelope (**FIGURE 6-17**). This type of flame is achieved when the proper proportions of oxygen and acetylene are being burned. The lighter blue tip of the innermost cone is the hottest part of the flame. The neutral flame is the most commonly used oxyacetylene flame for heating, cutting, and welding.

FIGURE 6-17 Neutral flame.

19. Direct the torch flame onto the metal to be heated. Position the flame so that the tip of the inner cone is at the metal.
20. When the area of the heated metal to be bent turns cherry red, remove the flame and close the oxygen flow control valve and the acetylene flow control valve on the torch handle. Bend or manipulate the metal as needed. Be extremely careful to avoid being burned by the hot metal.

Cutting

Using oxyacetylene equipment to cut metal requires the use of a cutting attachment and cutting tip (or cutting torch) that is appropriate for the metal being worked on. Technicians should always use the cutting attachments and tips recommended by the equipment manufacturer. Technicians should also wear the proper PPE when preparing the equipment and cutting metal.

The basic process for cutting metal using oxyacetylene equipment is as follows:

1. Determine the type and thickness of the metal to be cut, and prepare the metal by removing any rust or debris. If necessary, mark the cutting line using a soapstone marker.
2. Follow the manufacturer's recommendations to select the proper cutting tip for the job.
3. Inspect the cutting tip for damage or plugged holes. Clean the tip with a tip cleaner if necessary.
4. Install and tighten the cutting attachment and tip according to the manufacturer's instructions.
5. Close the oxygen and acetylene flow control valves on the torch handle.
6. Loosen (back out) the adjusting screws on the oxygen and acetylene regulators.
7. Stand to the side of the oxygen cylinder and slowly open the cylinder valve until the proper pressure is indicated on the regulator working pressure gauge. Once the pressure on the cylinder pressure gauge rises, open the oxygen cylinder valve all the way.
8. Stand to the side of the acetylene cylinder and slowly open the cylinder valve until the cylinder pressure gauge on the regulator displays the cylinder pressure. Do not open the acetylene cylinder valve more than one and a half turns.
9. Open the oxygen flow control valve on the torch handle completely. Also, press and hold open the oxygen blast lever.
10. While the oxygen is flowing, tighten the adjusting screw on the oxygen regulator until the proper working pressure is displayed. Continue the oxygen flow for 10 seconds to purge the hoses and torch.
11. Release the oxygen blast lever and close the oxygen flow control valve on the torch handle.
12. Open the acetylene flow control valve on the torch handle approximately one-eighth of a turn.
13. While the acetylene is flowing, tighten the adjusting screw on the acetylene regulator until the proper working pressure is displayed. Continue the acetylene flow for 10 seconds to purge the hoses and torch.
14. Close the acetylene flow control valve on the torch handle.
15. Open the acetylene flow control valve on the torch handle approximately one-quarter turn.
16. Use a friction lighter to ignite the torch.
17. Use the acetylene flow control valve to increase the acetylene flow until the flame leaves the end of the heating tip and stops smoking. Then, decrease the acetylene flow until the flame returns to the tip.
18. Slowly open the oxygen flow control valve until a neutral flame is achieved.
19. Press the oxygen blast lever all the way down to check the flame pattern. The flame should have a long, thin cutting jet that extends as much as 8 inches (203 mm) from the cutting oxygen hole at the center of the tip (**FIGURE 6-18**). When the flame is correct, release the oxygen blast lever.
20. Position the torch perpendicular to the metal and approximately $\frac{1}{16}$ inch (1.6 mm) above the surface of the metal. Continue heating the metal until it begins to melt.
21. Depress the oxygen blast lever and, once the flame pierces the metal, start moving the torch slowly along the cut line. The torch movement should be in whichever direction provides the best visibility.
22. When the cut is complete, release the oxygen blast lever, remove the flame from the metal, and close the acetylene flow control valve and the oxygen flow control valve on the torch handle. Be extremely careful to avoid being burned by the hot metal.

Welding

The basic concept behind oxyacetylene welding is to heat two pieces of metal (the work metal) enough to form a small puddle of molten metal between them. Filler metal, typically in the form of a welding rod, is then placed into the molten puddle where it melts and fuses the two pieces of work metal together.

Using oxyacetylene equipment to weld metal requires the use of a welding tip that is appropriate for the metal being worked on. Technicians should always use the welding tips recommended by the equipment manufacturer. They should

FIGURE 6-18 Torch flame with cutting jet.

also wear the proper PPE when preparing the equipment and welding metal.

The basic process for welding metal using oxyacetylene equipment is as follows:

1. Determine the type and thickness of the metal to be welded and prepare the metal by removing any rust or debris.
2. Follow the manufacturer's recommendations to select the proper welding tip for the job.
3. Inspect the welding tip for damage or plugged holes. Clean the tip with a tip cleaner if necessary.
4. Install and tighten the welding tip according to the manufacturer's instructions.
5. Close the oxygen and acetylene flow control valves on the torch handle.
6. Loosen (back out) the adjusting screws on the oxygen and acetylene regulators.
7. Stand to the side of the oxygen cylinder and slowly open the cylinder valve until the proper pressure is indicated on the regulator working pressure gauge. Once the pressure on the cylinder pressure gauge rises, open the oxygen cylinder valve all the way.
8. Stand to the side of the acetylene cylinder and slowly open the cylinder valve until the cylinder pressure gauge on the regulator displays the cylinder pressure. Do not open the acetylene cylinder valve more than one and a half turns.
9. Open the oxygen flow control valve on the torch handle completely.
10. While the oxygen is flowing, tighten the adjusting screw on the oxygen regulator until the proper working pressure is displayed. Continue the oxygen flow for 10 seconds to purge the hoses and torch.
11. Close the oxygen flow control valve on the torch handle.
12. Open the acetylene flow control valve on the torch handle approximately one-eighth of a turn.
13. While the acetylene is flowing, tighten the adjusting screw on the acetylene regulator until the proper working pressure is displayed. Continue the acetylene flow for 10 seconds to purge the hoses and torch.
14. Close the acetylene flow control valve on the torch handle.
15. Open the acetylene flow control valve on the torch handle approximately one-quarter of a turn.
16. Use a friction lighter to ignite the torch.
17. Use the acetylene flow control valve to increase the acetylene flow until the flame leaves the end of the heating tip and stops smoking. Then, decrease the acetylene flow until the flame returns to the tip.
18. Slowly open the oxygen flow control valve until a neutral flame is achieved.
19. Position the torch so that the tip of the inner cone of the flame is just above the surface of the metal to be welded. Heat the two metals along a narrow welding path until a puddle of molten metal forms.
20. Place the end of the gas welding rod into the puddle and slowly move along the welding path to fuse the two metal pieces together. The filler metal and the molten metal from the two workpieces form a **bead** (FIGURE 6-19).

FIGURE 6-19 Oxyacetylene torch welding.

21. When the weld is complete, remove the flame from the metal and close the oxygen flow control valve and the acetylene flow control valve on the torch handle. Be extremely careful to avoid being burned by the hot metal.

► Oxyacetylene Brazing and Soldering

K06004

Oxyacetylene equipment can be used for brazing and soldering metals. Unlike welding, where extremely high temperatures are used to melt the base metals and the filler metal so that they fuse together, brazing and soldering use lower temperatures that only heat the base metals but melt the filler metal to bond the base metals together.

Brazing

Brazing is a method used to join two pieces of metal together by heating the metal pieces and then melting a brazing rod to bond the workpieces together through **adhesion**. The brazing rod material melts at a lower temperature than the metal pieces being joined together. The molten filler metal flows into the gap between the metal pieces through **capillary action**, which is essentially the adhesive force exerted by the surface of a metal to attract a dissimilar metal over its surface. When cooled, the filler metal bonds the workpieces together.

Brazing operations require temperatures above 800°F (427°C), but not as high as those used for welding. The temperature must be high enough to melt the brazing filler metal rod but low enough to not melt the base metal workpieces. Since the workpieces themselves are never melted together (only bonded together by a filler metal), they can be the same type of metal or different types of metal. This is a key advantage of brazing.

In order for brazing to work effectively, two important criteria must be met: (1) the two base metal workpieces must be very closely fitted, and (2) they must be extremely clean. Research has shown that joint clearances between 0.0012 and 0.0031 inches (0.03 and 0.08 mm) are an ideal range for brazing. However, acceptable joint clearances for brazing operations can

FIGURE 6-20 Brazed lap joint.

be as high as 0.024 inches (0.6 mm). Realistically, brazing two clean metal pieces that have been overlapped to form a lap joint should result in a very strong bond (FIGURE 6-20).

Proper cleaning of the base metal surfaces prior to brazing is usually accomplished using chemical solvents and/or abrasives. One important factor when using abrasives such as sandpaper to clean the metal surfaces is to maintain some roughness on the metal. Smoothing the metal surfaces too much interferes with the flow, or **wetting**, of the molten filler metal. A slightly rough surface provides better capillary action of the filler metal and, therefore, better joint strength.

In addition to cleaning the surfaces of the base metals, it is also necessary to maintain an environment that prevents oxides from forming on the metals when brazing is taking place. Preventing oxidation and removing contaminants during brazing operations is accomplished with **flux**. Flux comes in several forms, including paste, liquid, and powder, and it can be brushed on the metal surfaces being brazed (FIGURE 6-21). When heat is applied to the base metals, the flux melts and flows into the joint to remove impurities ahead of the filler metal. Many brazing filler metal rods have a flux coating or a flux core, which eliminates the need to add flux prior to brazing.

The basic process for brazing metal using oxyacetylene equipment is as follows:

1. Determine the type(s) of metal to be brazed and thoroughly clean the metal with a solvent and/or an abrasive pad.
2. Follow the equipment manufacturer's recommendations for selecting the proper welding tip and brazing filler metal rods for the job.

► TECHNICIAN TIP

If the brazing filler metal rods being used have a flux coating or a flux core, it may not be necessary to use additional flux to clean the joint prior to brazing.

3. Inspect the tip for damage and clean it with a tip cleaner if necessary.
4. Install and tighten the tip according to the manufacturer's instructions.
5. Close the oxygen and acetylene flow control valves on the torch handle.
6. Loosen (back out) the adjusting screws on the oxygen and acetylene regulators.
7. Stand to the side of the oxygen cylinder and slowly open the cylinder valve until the proper pressure is indicated on the regulator working pressure gauge. Once the pressure on the cylinder pressure gauge rises, open the oxygen cylinder valve all the way.

FIGURE 6-21 Worker applying flux paste prior to brazing.

8. Stand to the side of the acetylene cylinder and slowly open the cylinder valve until the cylinder pressure gauge on the regulator displays the cylinder pressure. Do not open the acetylene cylinder valve more than one and a half turns.
9. Open the oxygen flow control valve on the torch handle completely.
10. While the oxygen is flowing, tighten the adjusting screw on the oxygen regulator until the proper working pressure is displayed. Continue the oxygen flow for 10 seconds to purge the hoses and torch.
11. Close the oxygen flow control valve on the torch handle.
12. Open the acetylene flow control valve on the torch handle approximately one-eighth of a turn.
13. While the acetylene is flowing, tighten the adjusting screw on the acetylene regulator until the proper working pressure is displayed. Continue the acetylene flow for 10 seconds to purge the hoses and torch.
14. Close the acetylene flow control valve on the torch handle.
15. Open the acetylene flow control valve on the torch handle approximately one-quarter of a turn.
16. Use a friction lighter to ignite the torch.
17. Use the acetylene flow control valve to increase the acetylene flow until the flame leaves the end of the heating tip and stops smoking. Then, decrease the acetylene flow until the flame returns to the tip.
18. Slowly open the oxygen flow control valve until a **carburizing flame** is achieved. Brazing can be performed with a neutral flame, but a carburizing flame is preferable. A carburizing flame is sootier and cooler than a neutral flame, which helps remove oxides from the surface of copper. A carburizing flame can be identified visually because its inner cone is longer and less defined than that of a neutral flame (FIGURE 6-22). To achieve a carburizing flame, simply adjust the flow control valves on the torch handle to provide a bit more acetylene than oxygen to the gas mix.
19. Direct the torch flame approximately 2 inches (51 mm) above the surface of the metal to be brazed, starting on each side of the joint and moving inward toward the joint.

FIGURE 6-22 Carburizing flame compared to neutral flame.

- 20.** Continue to heat the metal until it turns dark red, but stop before the metal shows signs of melting. Then, remove the torch flame from the metal.
- 21.** Touch the tip of the brazing rod to the metal and observe the capillary action as the rod melts and the filler metal flows into the joint. When the joint appears to have been adequately filled, remove the brazing rod and close the oxygen and acetylene flow control valves on the torch handle. Be extremely careful to avoid being burned by the hot metal.
- 22.** Allow the metal to cool, or dip it into water to hasten the cooling process. Remove any excess flux from the joint with a wire brush.

Soldering

Soldering is a method used to join two pieces of metal together by heating the metal pieces and then melting a soldering rod or soft solder material to bond the workpieces together through adhesion. The soldering material melts at a lower temperature than the metal pieces being joined together. The molten filler metal flows between the metal pieces through capillary action and, when cooled, bonds the workpieces together.

Soldering operations are typically done at temperatures around 500°F (260°C), since that is the temperature at which silver soldering rods melt. The temperature must be high enough to melt the soldering filler metal but low enough to not melt the base metal workpieces. Since the workpieces themselves are never melted together (only bonded together by a filler metal), they can be the same type of metal or different types of metal.

Because of the relatively low temperatures involved in soldering operations, soldered joints are among the weakest joints formed in oxyacetylene applications. However, if done properly, soldered joints can withstand a great deal of abuse and, in electrical applications, maintain electrical connectivity at terminals and connectors.

For soldering to work effectively, the two base metal workpieces must be very closely fitted—that is, they must have a well-defined seam—and they must be extremely clean. Joint clearances for most soldering jobs should be about 0.005 inches

(0.13 mm). Proper cleaning of the base metal surfaces prior to soldering is usually done with chemical solvents and/or abrasives. If abrasives are used to clean the metal surfaces, it is desirable to maintain some roughness on the metal to enable the proper capillary action of the solder.

To prevent oxidation and remove impurities, flux should be applied to the metal during the soldering process. Some solder filler rods have a flux coating or a flux core, which can eliminate the need to add additional flux prior to soldering.

The basic process for soldering metal using oxyacetylene equipment is as follows:

- 1.** Determine the type(s) of metal to be soldered and thoroughly clean the metal with a solvent and/or an abrasive pad.
- 2.** Follow the equipment manufacturer's recommendations for selecting the proper welding tip and soldering filler metal rods for the job.
- 3.** Inspect the tip for damage and clean it with a tip cleaner if necessary.
- 4.** Install and tighten the tip according to the manufacturer's instructions.
- 5.** Close the oxygen and acetylene flow control valves on the torch handle.
- 6.** Loosen (back out) the adjusting screws on the oxygen and acetylene regulators.
- 7.** Stand to the side of the oxygen cylinder and slowly open the cylinder valve until the proper pressure is indicated on the regulator working pressure gauge. Once the pressure on the cylinder pressure gauge rises, open the oxygen cylinder valve all the way.
- 8.** Stand to the side of the acetylene cylinder and slowly open the cylinder valve until the cylinder pressure gauge on the regulator displays the cylinder pressure. Do not open the acetylene cylinder valve more than one and a half turns.
- 9.** Open the oxygen flow control valve on the torch handle completely.
- 10.** While the oxygen is flowing, tighten the adjusting screw on the oxygen regulator until the proper working pressure is displayed. Continue the oxygen flow for 10 seconds to purge the hoses and torch.
- 11.** Close the oxygen flow control valve on the torch handle.
- 12.** Open the acetylene flow control valve on the torch handle approximately one-eighth of a turn.
- 13.** While the acetylene is flowing, tighten the adjusting screw on the acetylene regulator until the proper working pressure is displayed. Continue the acetylene flow for 10 seconds to purge the hoses and torch.
- 14.** Close the acetylene flow control valve on the torch handle.
- 15.** Open the acetylene flow control valve on the torch handle approximately one-quarter of a turn.
- 16.** Use a friction lighter to ignite the torch.
- 17.** Use the acetylene flow control valve to increase the acetylene flow until the flame leaves the end of the heating tip and stops smoking. Then, decrease the acetylene flow until the flame returns to the tip.
- 18.** Slowly open the oxygen flow control valve and then adjust the two flow control valves so that a bit more acetylene than

FIGURE 6-23 Soldering a pipe elbow.

oxygen is being provided to the gas mix and a carburizing flame is achieved.

19. Direct the torch flame approximately 2 inches (51 mm) above the surface of the metal to be soldered, starting on each side of the joint and moving inward toward the joint.
20. Continue to heat the metal until it turns red, but stop before the metal shows signs of melting.

► TECHNICIAN TIP

Some metals might not turn red to indicate that they are hot enough for solder to be applied. In these cases, it is best to observe the condition of any flux that has been applied to the joint. When the flux melts and becomes clear, the joint is hot enough to melt the solder filler material.

21. When the base metal appears to be hot enough, remove the torch flame and touch the tip of the soldering rod to the metal (**FIGURE 6-23**). Observe the capillary action as the rod melts and the filler metal flows into the joint. When the joint appears to have been adequately filled, remove the soldering rod and close the oxygen and acetylene flow control valves on the torch handle. Be extremely careful to avoid being burned by the hot metal.
22. Allow the metal to cool or dip it into water to hasten the cooling process. Remove any excess flux from the joint with a wire brush.

► Oxyacetylene Welding Repair Techniques

K06005

Numerous techniques can be used to make oxyacetylene welding applicable to many different applications. The specific technique used can depend on factors such as the type and thickness of the metal being welded, the type of preparation needed for the metal, and the positioning and movement of the welding torch and welding filler rod.

Base Metal Preparation

An important part of oxyacetylene welding repair involves preparing the metal to be welded. No matter how thin or thick the metal workpieces are, they need to be cleaned and properly positioned before welding begins. In some cases, it may be necessary to tack weld the workpieces to hold them in position for welding or to gap the pieces to allow for expansion and contraction. Thicker metals may have to be beveled to create a suitable joint for the welding bead (**FIGURE 6-24**).

FIGURE 6-24 Preparing workpieces for welding.

WELDING TYPES	WELDING JOINTS	WELDING POSITIONS			
		FLAT	HORIZONTAL	VERTICAL	OVERHEAD
GROOVE WELDS	BUTT				
	CORNER				
FILLET WELDS	TEE				
	LAP				

FIGURE 6-25 Welding positions, types, and joints.

Welding positions, welding types, and welding joints can vary from job to job (**FIGURE 6-25**). Four welding positions that service technicians are likely to use include flat, horizontal, vertical, and overhead. In addition, two common welding types are groove welds and fillet welds, and four common welding joints are butt, corner, tee, and lap.

Groove welds are done on beveled surfaces. This allows the molten base metal and filler metal to fill the prepared joint groove to create a strong connection. Fillet welds, on the other hand, do not require beveling. They are often performed on metal plates that are aligned perpendicular to one another.

Forehand and Backhand Welding

There are two fundamental techniques used for oxyacetylene welding: **forehand welding** and **backhand welding**. These two techniques are referred to by numerous other names, as well. For instance, forehand welding is sometimes called the leftward technique, forward welding, push welding, puddle welding, and ripple welding. Backhand welding is sometimes called the rightward technique, backward welding, drag angle welding, and pull welding. Regardless of the name used, the two methods differ in several ways.

Forehand welding is best suited for welding metals that are relatively thin—typically less than one-eighth of an inch (or 3–5 mm) thick. With this technique, the welding torch is held in the right hand and the filler rod is held in the left hand. Welding begins on the right side of the seam and moves toward the left side of the seam (**FIGURE 6-26**). The torch flame is directed away from the finished weld and pushed in the direction of the welding, which allows it to preheat the

**FIGURE 6-26** Forehand welding technique.

joint before the filler rod is melted. The filler rod is angled toward the finished weld and moved in a backward and forward motion.

Backhand welding is typically used for thicker metals. With this technique, the welding torch is held in the right hand and the filler rod is held in the left hand. Welding begins on the left side of the seam and moves toward the right side of the seam (**FIGURE 6-27**). The torch flame is directed toward the finished weld and pulled in the direction of the welding. The filler rod is angled away from the finished weld and moved in a circular motion.

As a general rule, the backhand welding technique requires less filler material and gas usage while resulting in better weld properties than the forehand welding technique. And since many MORE welding jobs involve thick metals, service technicians are more likely to use this welding technique.

FIGURE 6-27 Backhand welding technique.

► Industry/Accreditation

I06001, S06001

The terminology associated with the composition and use of oxyacetylene equipment is critical for MORE service technicians. Technicians must be able to accurately use terminology that is common to the trade and understand safety procedures that apply to this work. Federal and state agencies along with industrial trade groups have developed standards over the years that technicians can use for source material:

- The Occupational Safety and Health Administration (OSHA) at www.osha.gov, which sets and enforces standards related to safety and equipment.
- The National Fire Protection Association (NFPA) at www.nfpa.org, a global nonprofit organization devoted to eliminating death, injury, property, and economic losses due to fire, electrical, and related hazards. See Standard 51, *Standard for the Design and Installation of Oxygen-Fuel Gas Systems for Welding, Cutting, and Allied Processes*; Standard 51B, *Standard for Fire Prevention During Welding, Cutting, and Other Hot Work*; and Standard 55, *Compressed Gases and Cryogenic Fluids Code*.

- The American Welding Society (AWS) at www.aws.org, a nonprofit organization with a global mission to advance the science, technology, and application of welding and allied joining and cutting processes, including brazing, soldering, and thermal spraying.
- The American National Standards Institute (ANSI) at www.ansi.org, an organization that oversees the creation, promulgation, and use of norms and guidelines that impact U.S. businesses. See Standard Z49.1 *Safety in Welding, Cutting, and Allied Processes*.

In addition, oxyacetylene equipment manufacturers and magazines covering the welding industry typically have technical information, including glossaries, available on their websites. Technicians working on MORE should exploit all available resources to ensure that they understand the terminology and regulations that apply to the trade. To correctly cut, weld, solder, and braze metals, follow the guidelines in

SKILL DRILL 6-1.

► Attitude

A06001

Before setting up and using any type of oxyacetylene equipment, it is critical for MORE service technicians to be thoroughly familiar with the safety regulations and procedures that pertain to the equipment and its use for heating, cutting, and welding metal. This includes locating and reading any safety-related manuals that may exist on site. Find out where those manuals are normally kept and take action to obtain the proper manuals for the equipment. If printed manuals are not available for the equipment, try to find electronic versions either from the client or online through the equipment manufacturer's website. It might also be possible to find the appropriate material by searching online. In some cases, it might be necessary to call the equipment manufacturer to get the needed information. Whatever means you use, it is important to ensure that the resource material being used matches the equipment and the procedures being performed.

SKILL DRILL 6-1 Cutting, Welding, Soldering, and Brazing Metals

1. Obtain and review the necessary manuals that pertain to safety practices and the PPE needed, the setup and operation of the oxyacetylene equipment, and the procedures to be used.

2. Using the equipment manufacturer's manuals, set up and leak test the oxyacetylene equipment, and gather the recommended attachments and tips needed to perform the work.

3. Following the equipment manufacturer's guidelines, set the pressures and flows for the oxygen and acetylene, light and adjust the torch to achieve the proper flame pattern, and position the torch flame to heat and cut through the metal.

(Continued)

SKILL DRILL 6-I Cutting, Welding, Soldering, and Brazing Metals (Continued)

4. Following the equipment manufacturer's guidelines, set the pressures and flows for the oxygen and acetylene, light and adjust the torch to achieve the proper flame pattern, and position the torch flame and filler metal rod to heat and weld two pieces of metal.

5. Following the equipment manufacturer's guidelines, set the pressures and flows for the oxygen and acetylene, light and adjust the torch to achieve the proper flame pattern, and position the torch flame and filler metal rod to heat and fuse two pieces of metal.

6. Following the equipment manufacturer's guidelines, set the pressures and flows for the oxygen and acetylene, light and adjust the torch to achieve the proper flame pattern, and position the torch flame and filler metal rod to heat and braze two pieces of metal.

► Wrap-Up

Ready for Review

- ▶ The major components that make up a typical oxyacetylene outfit include an acetylene cylinder, an oxygen cylinder, a pressure regulator for each cylinder, a flashback arrestor on the outlet of each regulator, a hose for each gas, a check valve (or a second flashback arrestor) at the end of each hose, and a torch.
- ▶ Each cylinder has a pressure regulator with two gauges: a cylinder pressure gauge that shows how much pressure is in the cylinder and a working pressure gauge that shows how much pressure is in the hose, or line.
- ▶ Flashback arrestors are spring-loaded valves that prevent a flame from traveling back up the hose to the cylinders.
- ▶ Check valves allow flow in one direction only.
- ▶ Oxyacetylene hoses are typically color coded: red for acetylene and green for oxygen. To prevent interchanging gas pathways through the equipment, acetylene connections use left-hand threads and oxygen right-hand threads.
- ▶ A torch handle usually has flow control valves for adjusting the flow of oxygen and acetylene and a threaded outlet for different tips and attachments for heating, cutting, and welding.
- ▶ There are many types of tips available for oxyacetylene torches, including those designed specifically for heating, cutting, welding, brazing, and soldering.
- ▶ Some common supplemental components used with oxyacetylene equipment include wrenches, strikers, tip cleaners, and filler metals.
- ▶ The pressure inside a full cylinder of acetylene is approximately 250 psi (1,724 kPa), while the pressure in an oxygen cylinder is approximately 2,200 psi (15,168 kPa).
- ▶ When acetylene is mixed with oxygen, very high flame temperatures of 6,300°F to 6,800°F (3,480°C to 3,760°C) are produced.
- ▶ Technicians should always wear appropriate PPE when heating, cutting, or welding with oxyacetylene equipment.
- ▶ Breathing masks or respirators may be required when heating, cutting, or welding materials that can produce toxic fumes when heated with a torch.
- ▶ To minimize the risk of fire and explosion, technicians should always inspect and prepare the machinery or equipment to be worked on, as well as the work area and its surroundings before using oxyacetylene equipment.
- ▶ If the work area is a confined space or if it requires a hot-work permit or a fire watch, follow all requirements and procedures for the site to avoid serious injuries and penalties.
- ▶ Make sure that the work area is properly ventilated by using fans, exhaust hoods, or ventilated booths.
- ▶ Always follow safety guidelines related to the storage of oxyacetylene equipment that is not in use.
- ▶ Oxygen cylinders and acetylene cylinders must be secured separately in a safe area at least 20 feet (6 meters) apart or separated by a wall that is 5 feet (1.5 meters) high with a minimum 30-minute burn rating.
- ▶ If technicians are required to set up oxyacetylene equipment, they must follow all the applicable safety precautions, wear the appropriate PPE, use the equipment manufacturer's guidelines for setup, and leak test all connections before use.
- ▶ Factors that must be considered during oxyacetylene-heating, cutting, and welding processes include the type

and thickness of the metal involved, the equipment manufacturer's recommendations for torch attachments and tips, the flows and pressures of the oxygen and acetylene, the torch flame profile, and the technique used to accomplish the task.

- ▶ Brazing is a method used to join two pieces of metal together by heating the metal pieces to above 800°F (427°C) and then melting a brazing rod to bond the workpieces together through adhesion.
- ▶ When brazing rod material melts, it flows into the gap between the metal workpieces through capillary action and, when cooled, bonds the workpieces together.
- ▶ A key advantage of brazing is that it can be used to bond together the same type of metal or different types of metal.
- ▶ Soldering is a method used to join two pieces of metal together by heating the metal pieces to about 500°F (260°C) and then melting a soldering rod or soft solder material to bond the workpieces together through adhesion.
- ▶ When soldering material melts, it flows between the metal workpieces through capillary action and, when cooled, bonds the workpieces together.
- ▶ Since the workpieces themselves are never melted together (only bonded together by a filler metal), soldering can be used to bond the same type of metal or different types of metal.

Key Terms

adhesion The bonding property that occurs when two metals are joined together using molten filler metal to fill the gap between them.

American National Standards Institute (ANSI) An organization that oversees the creation, promulgation, and use of norms and guidelines that impact U.S. businesses.

backhand welding A welding technique (also called the rightward technique, backward welding, drag angle welding, and pull welding) best suited for thick metals in which the welding torch is held in the right hand, the filler rod is held in the left hand, and the welding direction moves from the left side of the seam toward the right side of the seam.

bead The deposit of filler metal and/or base metal along a joint or seam that results from a welding process.

capillary action The ability of a liquid, such as molten filler metal, to flow into narrow gaps between two objects. The adhesive properties of a metal's surface for dissimilar metals are directly related to capillary action.

carburizing flame A torch flame that has an excess of acetylene in the oxyacetylene fuel mix and is characterized by a sootier flame using an inner flame cone that is longer and less defined than that of a neutral flame.

check valve A type of valve that allows the flow of gas or liquid in one direction only.

confined space An enclosed area that has limited space and accessibility and requires special safety procedures for entering into, working in, and exiting it.

cylinder pressure gauge The gauge on an oxygen or acetylene regulator that shows how much pressure is in the cylinder.

dross Oxidized and molten metal waste (slag) that is left over during oxyacetylene cutting and welding operations.

flashback An unintentional ignition of oxygen and acetylene inside a torch handle that, if left unimpeded, can travel backward through the torch, hoses, and regulators into the cylinders.

flashback arrestor A spring-loaded valve installed on oxyacetylene equipment as a safety device to prevent flame from entering the torch hoses and traveling backward to the cylinders.

flux A material that is used during brazing and soldering operations to prevent oxidation and remove impurities from the metals.

forehand welding A welding technique (also called the leftward technique, forward welding, push welding, puddle welding, and ripple welding) best suited for relatively thin metals in which the welding torch is held in the right hand, the filler rod is held in the left hand, and the welding direction moves from the right side of the seam toward the left side of the seam.

leak test solution A soapy liquid that, when placed on oxyacetylene equipment connections, can indicate leaks by bubbling.

MFA A shortened term for multiple flame acetylene torch tip, which is a type of oxyacetylene torch tip used for heating metal.

neutral flame A torch flame that has the correct proportions of oxygen and acetylene and is characterized by one or more inner cones, which are light blue in color, surrounded by a darker blue outer flame envelope.

reamer Any of several round steel files found on a tip cleaner tool and used to clean tip orifices.

rosebud A type of torch tip with numerous holes in the end that produce multiple flames with a wide pattern suitable for heating metal.

spats A type of PPE, often made of leather, worn over the laces and tongue of work boots to protect workers from hot metal.

twin-line hose Oxygen and acetylene hoses that are connected together for most of their length.

wetting The flow of molten filler material during brazing and soldering operations.

working pressure gauge The gauge on an oxygen or acetylene regulator that shows how much pressure is in the hose, or line.

Review Questions

1. Removing the protective cap from an oxygen or acetylene cylinder reveals a _____.
 - a. flashback arrestor
 - b. check valve
 - c. pressure regulator
 - d. cylinder valve
2. The proper tool to use for lighting an oxyacetylene torch is a _____.
 - a. spatter
 - b. striker
 - c. flasher
 - d. rosebud

3. According to the American National Standards Institute (ANSI), a typical shade range for protective goggles used in oxyacetylene welding is from _____.
 - a. shade 0 to shade 2
 - b. shade 1 to shade 3
 - c. shade 3 to shade 6
 - d. shade 9 to shade 15
4. If a technician is going to be exposed to toxic fumes for a long period of time during a cutting or welding procedure, the technician should wear a _____.
 - a. full-face, supplied-air respirator (SAR)
 - b. high-efficiency particulate arresting (HEPA) filter
 - c. pure oxygen supply mask (POSM)
 - d. dampened charcoal canister mask (DCCM)
5. Cracking open the oxygen and acetylene cylinder valves before setting up an oxyacetylene outfit is done to _____.
 - a. reset the cylinder regulators
 - b. clear the valves of debris
 - c. premix and flame test the gases
 - d. purge the work area
6. Cutting through a piece of thick metal typically requires a technician to _____.
 - a. increase the acetylene pressure above 15 psig (103 kPa)
 - b. introduce a separate inert gas to the welding puddle
 - c. slowly push a reamer rod into the initial cut
 - d. depress and hold the oxygen blast lever on the torch
7. When brazing is used to join together two base metal workpieces, the heat from the torch flame _____.
 - a. melts only the base metal workpieces
 - b. melts one base metal workpiece and the brazing rod material
 - c. melts only the brazing rod material
 - d. melts both metal workpieces and the brazing rod material
8. Soldering operations are typically done at temperatures around _____.
 - a. 500°F (260°C)
 - b. 800°F (427°C)
 - c. 2,000°F (1,093°C)
 - d. 3,000°F (1,649°C)
9. Groove welds are most likely to be done on _____.
 - a. non-beveled surfaces
 - b. perpendicularly aligned metal plates
 - c. very thin metal sheets
 - d. beveled surfaces
10. Which welding technique involves angling the torch flame toward the finished weld while angling the filler rod away from the finished weld?
 - a. Leftward
 - b. Backhand
 - c. Forehand
 - d. Push

ASE Technician A/Technician B Style Questions

1. Technician A says the working pressure gauge on an oxygen regulator indicates how much pressure is in the cylinder. Technician B says the working pressure gauge shows how much pressure is in the hose, or line. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says a rosebud tip is used for heating metal. Technician B says a rosebud tip is used for cutting metal. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says acetylene should never be used at a pressure above 25 psig (172 kPa). Technician B says acetylene should never be used at a pressure above 20 psig (138 kPa). Who is correct?
 - a. Technician A
 - b. Technician B

CHAPTER 7

Shielded Metal Arc, MIG, and TIG Welding

Knowledge Objectives

After reading this chapter, you will be able to:

- **K07001** Describe shielded metal arc welding (SMAW) equipment and components.
- **K07002** Explain safety regulations for welding of metals using SMAW.
- **K07003** Select and use mild steel electrodes for shielded metal arc welding.
- **K07004** Describe air-arc gouging.

Skills Objectives

After reading this chapter, you will be able to:

- **S07001** Differentiate between MIG, TIG, and stick welding procedures.
- **S07002** Demonstrate the proper procedures to weld mild steel with shielded metal arc.
- **S07003** Demonstrate the procedures to weld mild steel using wire feed processes (MIG, TIG).

Attitude Objectives

After reading this chapter, you will be able to:

- **A07001** Locate and follow appropriate safety procedures when welding metal.

Industry/Accreditation

After reading this chapter, you will be able to:

- **I07001** Communicate trade-related information using standard terms for SMAW welding.
- **I07002** Recommend correct repair techniques for welding metal using SMAW procedures.

► Introduction

Service technicians working on heavy equipment are almost certain to use shielded metal arc welding (SMAW) at one time or another. SMAW, often called stick welding, is the most common form of arc welding used on MORE (mobile off-road equipment) machines. Two other forms of arc welding that technicians might also encounter are gas metal arc welding (GMAW), which is often referred to as metal inert gas (MIG) welding, and, to a lesser extent, gas tungsten arc welding (GTAW), which is often called tungsten inert gas (TIG) welding.

For service technicians to work safely and effectively with arc welding equipment, they must be familiar with the basic types of equipment, recognize and follow all safety guidelines associated with the equipment, and know how to set up and use the equipment to accomplish the necessary task. This chapter describes SMAW, MIG, and TIG welding equipment, examines safety regulations that apply to arc welding, and describes how to use arc welding equipment for various welding applications.

► Shielded Metal Arc Welding (SMAW) Equipment and Components

K07001, S07001

Shielded metal arc welding (SMAW), or stick welding, is the most commonly used form of arc welding. Stick welding uses the intense heat produced by an electric arc that is created between a base metal workpiece and the tip of a filler metal electrode (welding rod). The heat from the arc melts the workpiece metal along the welding joint as well as the filler metal electrode. As a result, the metals form a molten pool in which they fuse together through **coalescence** to form a strong welded bond.

There are numerous reasons why stick welding is the most popular form of arc welding. The equipment is relatively simple and inexpensive, and it can be used on most common metals and alloys. In addition, stick welding is generally easy to learn, requiring only a moderate amount of practice. The filler metal electrodes used in stick welding are widely available and have a flux coating that protects against oxidation, so no additional flux or shielding gas is needed. Furthermore, stick welding equipment is portable, which makes it a good choice for field service applications and limited access areas. Stick welding can

also be performed outdoors in less than ideal weather conditions (e.g., windy, damp conditions).

SMAW Equipment

The main components of a typical SMAW system include the welding machine, or **power source**, and its internal components; an electrode cable with an electrode stick holder, a work cable with a work clamp, a power supply cable that plugs into an electric outlet, an on/off power switch, an AC/DC (alternating-current/direct-current) output selector, and an amperage selector (**FIGURE 7-1**).

At its core, a basic stick welding machine like the type found in MORE maintenance facilities is essentially a **step-down transformer** that converts high-voltage, low-current AC power from a wall outlet (or engine) to a lower-voltage, higher-current AC or DC output. Any stick welder that provides DC output power includes a **rectifier** or some other means to convert the AC input power to a DC output. The AC/DC output selector allows a welding technician to select the form of output current. In addition, the amperage selector allows the welder to choose the amount of current needed for the welding operation (**FIGURE 7-2**).

FIGURE 7-1 Typical SMAW equipment.

You Are the Mobile Heavy Equipment Technician

A foreman at a construction site asks if you could weld a bracket that holds part of the blade adjustment mechanism on one of their crawler dozers. You think the bracket that the foreman is describing is near the engine compartment, but you won't know for sure until you see it. The foreman also mentions that the brackets appear to have been welded before. You'll need to take an arc welding rig to the site, but you have some questions to consider before you load up the equipment and go.

1. Would the thickness and type of metal that needs to be welded be a factor in which type of welding equipment you use?
2. Would the location of the bracket that needs welding pose any safety-related concerns?
3. Where might you find information about the proper electrodes and welding equipment settings to use during the welding job?
4. If the bracket broke at a previous weld, what might you need to carry to prepare for welding it again?

FIGURE 7-2 Output current controls on SMAW power source.

Stick welders can use a range of electrical power inputs, from 120V for small machines to 600V for large machines. In a typical configuration, a stick welder would convert an AC input power of 220V at 50 amps to a DC output of 25V at 125 amps. DC is the most common current used for stick welding. Unlike alternating current, DC flows in only one direction and results in easier arc starting and less sticking and spatter.

One critical aspect of SMAW is that the welding machine provides a **constant current** output. This means that the output current from the welding machine, which accounts for the intense heat at the arc, remains relatively constant even when there are variations in the welding conditions—such as when a welding technician varies the distance, or length, of the arc.

Another critical aspect of SMAW has to do with the **electrical polarity**, or the direction of current flow, in the welding circuit. The circuit starts at the power source (the SMAW machine) and includes the electrode cable and holder, the electrode, the base metal workpiece, and the work cable and clamp. When a DC output is used, one pole, or terminal, is always positive and the other pole is always negative. Connecting the electrode cable to the positive terminal of the SMAW power source and the work cable to the negative terminal of the power source sets up a **direct current electrode positive (DCEP)** connection (FIGURE 7-3). This is also referred to as a **reverse polarity** connection, and it is the most commonly used connection in stick welding because it provides the best welding results. Most electrodes are designed to be used in DCEP connections.

► TECHNICIAN TIP

If stick welding is being performed on a machine that has its own electrical system, there is a risk that the large amount of electric current passing through the machine could damage the machine's electrical components. For this reason, service technicians should disconnect the machine's battery ground cable and all onboard electronic control modules prior to welding.

SMAW Components and Accessories

Good-quality stick welding is possible only when the correct electrode is selected and used. Electrodes are available in many different sizes, wire materials, and coatings. Electrode sizes for SMAW range from $\frac{1}{16}$ -inch (1.6 mm) to $\frac{3}{8}$ inch (9.5 mm). The American Welding Society (AWS) provides a standard electrode classification system that service technicians should use

FIGURE 7-3 Welding circuit with DCEP connection showing current flow using electron theory.

TABLE 7-1 Common SMAW Electrodes

Standard AWS Electrode Name	Minimum Tensile Strength	Welding Positions	Flux Coating Material	Amount of Penetration	Output Current
E6010	60,000 psi (413,685 KPa)	All	Cellulose sodium	Deep	DC only
E6011	60,000 psi (413,685 KPa)	All	Cellulose potassium	Deep	DC/AC
E6013	60,000 psi (413,685 KPa)	All	Rutile potassium	Medium	DC/AC
E7018	70,000 psi (482,633 KPa)	All	Iron powder Low hydrogen	Shallow to medium	DC/AC

when selecting the proper electrode (**TABLE 7-1**). In this classification system, the electrode name is coded as follows:

- E = electrode
- the first two numbers = the tensile strength of the welded joint
- the third number = the acceptable welding position(s)
- the fourth number = the type of flux coating material, the amount of penetration, and the acceptable type of output current.

Since SMAW electrodes are consumed as they melt to provide filler metal, they must be replaced regularly. This is one disadvantage of stick welding when compared to other forms of arc welding.

In many stick welding jobs, the base metal workpieces being welded need to be held in place—at least until an initial weld has been completed. There are many types and sizes of clamps that can be used for this purpose (**FIGURE 7-4**). Some welding clamps are modified locking, or vise-grip, pliers. Other clamps are designed to hold workpieces at a 90-degree angle.

One drawback of stick welding relates to the **slag** that forms on the weld bead. This slag must be completely removed before another bead can be laid on top of the previous bead. Slag can be removed using a chipping hammer and a wire brush (**FIGURE 7-5**).

**FIGURE 7-4** Welding clamps.

MIG Welding

One form of arc welding that service technicians might encounter is called gas metal arc welding (GMAW). This form of welding is often called metal inert gas (MIG) welding because it requires the use of a shielding gas to protect the weld from oxidation and contaminants in the surrounding air. The three most commonly used gases are argon, carbon dioxide, and helium. Depending on the metal(s) being welded, two of these gases are often mixed.

► TECHNICIAN TIP

MIG welding is not suitable for outdoor use. This is because MIG welding requires the use of shielding gases, and any wind at the welding site can interfere with the gas flow and leave the weld vulnerable to oxidation and impurities.

MIG welding was developed during the 1940s as a way of speeding up welding processes, especially for supplies and equipment needed during World War II. It is perhaps the easiest form of arc welding to learn. In addition, MIG welding can be used to join a wide variety of metals. However, MIG welding is best suited for thin or medium-thickness metals and is most commonly used in high-volume production applications. Plus, the need for one or more shielding gas cylinders makes MIG welding equipment less portable.

**FIGURE 7-5** Chipping hammer and wire brushes for slag removal.

The basic equipment in a MIG welding outfit includes a welding machine, or power source; a shielding gas supply; an electrode wire feed reel, or spool; electrode wire; a welding gun; and a work return connection.

During operation, a technician presses a control switch, or trigger, on the welding gun to start the electric power, the electrode wire feed, and the shielding gas flow through a liner to the tip of the welding gun. The arc that is created at the tip of the welding gun produces intense heat—typically 6,000°F to 10,000°F (3,316°C to 5,538°C). This heat melts the base metal workpiece along the weld joint as well as the electrode wire. The shielding gas protects the molten weld pool so that the metals coalesce to form a strong weld. The work return, which is attached to the workpiece, completes the welding circuit back to the power source.

The power source of a MIG welding outfit converts AC power from an electrical source to DC output power. More specifically, the power source provides direct current, constant voltage power to the welding gun. The MIG welding process typically operates using a direct current electrode positive (DCEP) connection, also known as a reverse polarity connection.

Many types of electrode wire are available for MIG welding. Most electrode wire is available in one of four sizes: 0.024 inch (0.6 mm), 0.030 inch (0.8 mm), 0.035 inch (0.9 mm), or 0.045 inch (1.2 mm). Standards and recommendations have been developed over the years to help welders select the proper electrode wire for the type and thickness of the metal(s) being welded (FIGURE 7-6).

One of the most common electrode wire types used for general purpose welding of mild steel is ER70S-6. The designation for this electrode wire is based on the American Welding Society (AWS) A5.18 specification. Coding for the designation is as follows:

- ER = the filler metal can be used as an electrode or rod
- 70 = the tensile strength of the weld in 1,000 psi (6,895 KPa) increments or 70,000 psi (482,633 KPa) total

- S = the electrode wire is solid
- 6 = the chemical composition of the wire.

► TECHNICIAN TIP

The use of flux-core electrode wire is an option for MIG welding. Flux-core electrode wire eliminates the need for a shielding gas, which can improve the portability of the equipment. However, using flux-core electrode wire produces more slag. Most welders prefer to use solid-core electrode wire with a shielding gas.

TIG Welding

One form of arc welding that technicians could possibly encounter is gas tungsten arc welding (GTAW), which is often called tungsten inert gas (TIG) welding. TIG welding is most often used to weld thin pieces of metal, such as stainless steel or aluminum, but it can be used to weld many other types of metal, including steel, copper, brass, bronze, and numerous alloys. Service technicians do not often run into these applications, but they should be aware of how TIG welding works.

TIG welding uses a tungsten electrode to produce the electrical arc needed for welding. The tungsten electrode is not a consumable electrode as in other arc welding processes. Instead, it heats the base metal workpiece while a separate consumable tungsten filler rod is added to the weld puddle. An inert shielding gas is used to prevent oxidation and prevent impurities at the weld. Since two hands are needed to control the welding electrode and the filler rod, TIG welding is considered one of the more difficult arc welding methods.

The main components of a typical TIG welding outfit include a power source, a shielding gas cylinder with a regulator and valves, a coolant system (optional), a torch, a work cable and work clamp, and a foot-operated remote control (FIGURE 7-7). During operation, a welder starts the inert gas

Material	Suggested Wire Types, Polarity	Suggested Shielding Gases (Flow Rate of 20-30 cfh)	Wire Sizes (Diameters)	24 ga. (0.6 mm)	22 ga. (0.8 mm)	20 ga. (0.9 mm)	18 ga. (1.2 mm)	16 ga. (1.5 mm)	14 ga. (1.9 mm)	1/8" (3.2 mm)	3/16" (4.8 mm)	1/4" (6.4 mm)	5/16" (7.9 mm)

EXAMPLE: 4.5/65

FIGURE 7-6 MIG electrode wire selection chart.

FIGURE 7-7 GTAW (TIG) welding equipment setup.

flow through the TIG torch and positions the torch just above the metal to be welded. The welder then uses the foot pedal control to start an arc at the tungsten electrode in the torch. When the base metal workpiece begins to melt, the welder then adds the tungsten filler metal rod at the arc to fill the welding joint. In some TIG welding setups, cooling water flows through the torch to prevent the tungsten electrode from overheating.

The tungsten filler metal rods used in TIG welding are classified by AWS A5.12 and color coded to help technicians identify the correct rod to use for the welding application (**TABLE 7-2**).

In order to differentiate between MIG, TIG, and stick welding procedures, follow the steps in **SKILL DRILL 7-1**.

► Safety Regulations

K07002

Safety must be the foremost priority when working with any type of arc welding equipment. The intense heat and light produced by an electrical arc can pose a significant hazard to welders and other workers in the area. In addition, working around high-voltage and high-current electrical equipment presents a constant risk of electrical shock or electrocution. To ensure that they protect themselves and other personnel, technicians must follow all safety rules related to clothing and protective gear, the work area environment, and the way they use arc welding equipment.

Personal Protective Equipment

Technicians should always wear appropriate PPE when using arc welding equipment (**FIGURE 7-8**). The exact protective equipment that is needed can vary according to regulations and company standards, the welding activity being performed, and the work environment, but all clothing and protective gear should be dry and free of holes.

As a general rule, the following PPE should be worn during arc welding activities:

- A solid material (non-mesh) hat made of flame-retardant material. The bill of the hat should be facing to the rear.
- A welding helmet or, at a minimum, tight-fitting welding goggles with the proper light-reducing shade for the work being done. The Occupational Safety and Health Administration (OSHA), the American National Standards Institute (ANSI), and the American Welding Society (AWS) publish shade range guides for various types of welding and cutting activities. OSHA's shade range guide for arc welding work is from shade 7 to shade 11, while ANSI and AWS guidelines recommend shade 10 to shade 14 (**TABLE 7-3**).

► TECHNICIAN TIP

Many welding helmets available today feature auto-darkening technology. When an arc is struck, the lens of the helmet darkens to its shade setting within fractions of a second.

TABLE 7-2 Tungsten Filler Rod Classifications

COMMON TUNGSTEN ELECTRODE TYPES & SIZES			
ISO 6848 COLOR CHART	TYPE	SIZE	
		INCHES	MILLIMETERS
2% Thoriated Red AWS A5.12 EWTh-2 ISO 6848 WT20	Good D/C arc starts and stability, medium erosion rate, medium amperage range, medium tendency to spit.	.020 x 7"	0.5 x 175mm
		.040 x 7"	1.0 x 175mm
		1/16 x 7"	1.6 x 175mm

		5/32 x 7"	4.0 x 175mm
		.020 x 7"	0.5 x 175mm
		.040 x 7"	1.0 x 175mm
		1/16 x 7"	1.6 x 175mm
2% Ceriated Gray AWS A5.12 EWCe-2 ISO 6848 WC20 <i>(Formerly Orange)</i>	Excellent arc stability. Low erosion rate, best at low amperage range, no spitting, good D/C arc starts and stability.	3/32 x 7"	2.4 x 175mm
		1/8 x 7"	3.2 x 175mm
		5/32 x 7"	4.0 x 175mm
		.020 x 7"	0.5 x 175mm
		.040 x 7"	1.0 x 175mm
Pure Green AWS A5.12 EWP ISO 6848 WP	Balls easy, tends to spit at higher amperages. Used for non-critical welds only.	1/16 x 7"	1.6 x 175mm
		3/32 x 7"	2.4 x 175mm
		1/8 x 7"	3.2 x 175mm
		5/32 x 7"	4.0 x 175mm
		.020 x 7"	0.5 x 175mm

SKILL DRILL 7-1 Differences Between SMAW, MIG, and TIG

1. Using SMAW equipment manuals, carefully examine the SMAW equipment setup to identify the components and applicable settings involved in a stick welding process.

2. Wearing all the appropriate personal protective equipment (PPE), perform a test welding exercise using SMAW to familiarize yourself with the fundamentals of the stick welding process.

3. Using MIG welding equipment manuals, carefully examine the MIG equipment setup to identify the components and applicable settings involved in a MIG welding process.

SKILL DRILL 7-1 Differences Between SMAW, MIG, and TIG (Continued)

4. Wearing all the appropriate PPE, perform a test welding exercise using MIG equipment to familiarize yourself with the fundamentals of the MIG welding process.

5. Using TIG welding equipment manuals, carefully examine the TIG equipment setup to identify the components and applicable settings involved in a TIG welding process.

6. Wearing all the appropriate PPE, perform a test welding exercise using TIG equipment to familiarize yourself with the fundamentals of the TIG welding process.

FIGURE 7-8 Typical personal protective equipment.

SAFETY TIP

Sunglasses should not be worn as a substitute for welding goggles because they do not filter the extreme ultraviolet light as effectively. In addition, the plastic used in the lenses of sunglasses will not protect your eyes from sparks.

- A face shield over the welding goggles to protect the face from flying sparks, debris, and heat.
- Earmuffs (or earplugs) to minimize noise and protect ear canals from sparks.

SAFETY TIP

In some applications, such as welding material overhead, a full leather hood with a properly tinted face plate is preferable to wearing separate welding goggles and a face shield. In addition, if a hard hat is required in the work area, the hard hat must be able to accommodate face-shield and rear deflector attachments.

TABLE 7-3 Arc Welding Shade Range Guidelines

Operation	Electrode Size – inch (mm)	Arc Current (Amperes)	OSHA Minimum Protective Shade Number	ANSI & AWS Shade Number Recommendations*
Shielded Metal Arc Welding (SMAW)	Less than 3/32 (2.4)	Fewer than 60	7	-
	3/32–5/32 (2.4–4.0)	60–160	8	10
	More than 5/32–1/4 (4.0–6.4)	More than 160–250	10	12
	More than 1/4 (6.4)	More than 250–550	11	14
Gas Metal Arc Welding (GMAW) and Flux Cored Arc Welding (FCAW)		Fewer than 60	7	-
		60–160	10	11
		More than 160–250	10	12
		More than 250–550	10	14
Gas Tungsten Arc Welding (GTAW)		Fewer than 50	8	10
		50–150	8	12
		More than 150–500	10	14

- A protective leather apron or, at a minimum, flame-retardant clothing capable of protecting against ultraviolet light and hot sparks. Shirts should have long sleeves, pants should have no cuffs, and jackets should have no pockets where hot metal can collect.
- Long leather welding gloves to protect hands and arms.
- Leather work boots. The tongue and lace area of each boot should be tall enough to be covered by the pants legs. Otherwise, leather **spats** should be used to cover the front of the boots.

While working around the electricity and high heat associated with welding, technicians should not wear jewelry or body-piercing studs. These items can snag on equipment, absorb heat from the welding arc, and provide an unintended path for electrical current.

Breathing masks or respirators may be required when welding certain materials. For example, copper, lead, mercury, zinc, and other materials can produce toxic fumes when heated. For short-term exposure to some fumes, a technician may be safe using a high-efficiency particulate arresting (HEPA) filter or a metal-fume filter. But if a technician is exposed to such toxic fumes for a long period of time, a full-face, supplied-air respirator (SAR) is necessary (**FIGURE 7-9**).

Work Area Safety

Whenever arc welding equipment is used, there is an inherent risk of electrical shock, fire, and explosion. To minimize these and other risks, technicians should always inspect and prepare the machinery or equipment to be worked on, as well as the work area and its surroundings before using any arc welding equipment. Maintaining a safe work area typically includes the following:

- Remove flammable materials such as rags, paper, boxes, and flammable liquids from the work area or shield them using a fire-resistant cover. Many work site fires are caused by cutting and welding activities, so maintaining a neat and clean work area can greatly reduce accidental fires.

FIGURE 7-9 Worker wearing a supplied-air respirator (SAR).

- Set up flash shields or flash curtains to help isolate the intense light and heat of the welding area.
- Make sure that approved fire extinguishers are readily accessible before starting any welding operation.
- Make sure welding equipment is properly positioned at the work site and that all electrode and work cables are kept out of the way to avoid trip hazards.
- Determine whether the work area is a **confined space** or if it requires a hot-work permit or a fire watch. If so, follow all requirements and procedures for the site. Many sites require hot-work permits and fire watches, and failure to abide by these requirements can lead to serious injuries, penalties, and loss of equipment and structures due to fire.
- Make sure that the work area is properly ventilated. This is especially true for confined spaces. Fans, exhaust hoods, and ventilated booths can all be used to provide the necessary ventilation.
- Do not use oxygen to ventilate a work area. Releasing a large amount of oxygen into the work space can cause rapid and uncontrolled combustion if a spark ignites flammable material. Oxygen should be kept away from petroleum products to prevent fire and explosions.

Safe Equipment Use

Before starting any welding procedure, technicians must prepare the welding work area, properly set up the welding equipment, prepare the metal to be welded, and then follow appropriate safety guidelines for operating the welding equipment. Safe equipment use typically includes the following:

- While working, avoid breathing in welding fumes and smoke. Use a fan, if necessary, to divert the fumes and smoke. Wear an appropriate breathing apparatus to avoid toxic fumes when necessary.
- Never use oxygen to blow dust and dirt off clothing or equipment. Oxygen can remain trapped in clothing and ignite and burn rapidly if exposed to a spark.
- When using MIG welding equipment, do not press the control switch, or trigger, on the welding gun until you are ready to begin the welding process.
- Never point a welding gun toward others.
- Do not overuse welding equipment to a point where the equipment begins to overheat.
- Always connect the work cable clamp as closely as possible to the welding area to minimize the distance that the welding current has to travel.
- Ensure that all scrap metal or slag being discarded has cooled to a point where it does not pose a fire hazard.

► Shielded Metal Arc Welding of Mild Steel

K07003, S07002, S07003

Many of the welding activities that MORE (mobile off-road equipment) service technicians will encounter involve the use of SMAW on mild steel. Mild steel is basically a low-carbon

FIGURE 7-10 SMAW E6010 electrodes.

steel (0.25% or less carbon) that is used in countless everyday applications. It is not brittle. It can be heated and bent, as well as welded with relative ease. To achieve satisfactory results when welding mild steel, technicians need to follow the welding equipment guidelines for selecting the proper electrode and using the proper welding technique.

Selecting Mild Steel Electrodes

Selecting the proper electrode for SMAW is not particularly challenging. In fact, an E6010 electrode is perfectly capable of handling most general steel repairs that MORE service technicians are likely to face (FIGURE 7-10). The E6010 electrode is a good general purpose electrode that is available in various sizes to fit most SMAW needs.

There are, of course, other electrodes that might be more suitable for particular applications. Electrode manufacturers provide selection charts that technicians should always use for choosing the proper electrode (TABLE 7-4).

Welding Mild Steel

The amount of current (amps) needed to weld depends on numerous factors, including the thickness of the metal being welded, the diameter of the electrode being used, and the position being used during the welding process. As expected, thinner metals and smaller electrodes require less current than thicker metals and larger electrodes. Service technicians should always follow the electrode manufacturer's recommendations for equipment settings.

The basic procedure for welding mild steel using SMAW equipment is as follows:

Stick welding equipment setup and operation is as follows:

1. Ensure that the work area has been properly set up for the welding activity.
2. Determine the type(s) of metal to be welded and thoroughly clean the metal with a solvent and/or an abrasive pad to remove any rust or contamination. Ensure that the welding area and all materials are completely dry of water or any cleaning liquids that were used.

3. Use the electrode manufacturer's selection guide to select the proper electrode for the job.
4. Connect the electrode cable and the work cable to the welding machine in the proper position for the type of welding to be done (DC positive, DC negative, or AC).
5. Set the amperage on the machine according to the electrode manufacturer's guidelines.
6. Connect the work clamp to the base metal workpiece as close to the weld area as possible.
7. Put on all the appropriate PPE required for the job.
8. Turn on the welder and place the appropriate electrode into the electrode holder.

SAFETY TIP

If using a welding helmet that does not have an auto-darkening feature, be sure to lower the front of the welding helmet before initiating an arc to prevent eye damage.

9. Scratch or tap the tip of the electrode against the workpiece to start the arc.
10. Maintain the proper electrode angle, movement, and travel speed as the electrode is consumed.

TECHNICIAN TIP

It may be necessary to adjust the amperage setting on the power source if the weld does not appear to be satisfactory. Follow the equipment manufacturer's recommendations if an amperage adjustment is needed.

11. When the electrode is almost completely consumed, quickly pull the electrode holder away from the weld to interrupt the arc.
12. Allow the bead to cool, and then completely remove the slag using a chipping hammer and a wire brush.
13. If additional beads are needed, repeat the process to initiate the arc and continue the welding. Be sure to remove the slag from each added bead before continuing.
14. When the welding job is complete, turn off the power source and remove the work clamp from the workpiece.

SAFETY TIP

Remember that the weld area will remain hot for quite a while. Allow ample time for the workpiece to cool before touching it. Also, any slag that has been removed from the bead(s) should be allowed to cool before it is disposed of.

In order to demonstrate the proper procedures for welding mild steel using shielded metal arc welding, follow the steps in **SKILL DRILL 7-2**.

In order to demonstrate the proper procedures for welding mild steel using wire feed processes (MIG, TIG), follow the steps in **SKILL DRILL 7-3**.

TABLE 7-4 SMAW Electrode Selection Chart

ELECTRODE SELECTION CHART					
ELECTRODE	AC	DC *	POSITION	PENETRATION	USAGE
6010	NO	EP	ALL	DEEP	MIN, PREP, ROUGH, HIGH SPATTER
6011	YES	EP	ALL	DEEP	
6013	YES	EP, EN	ALL	LOW	GENERAL, EASY
7014	YES	EP, EN	ALL	MED	SMOOTH, EASY, FAST
7018	YES	EP	ALL	LOW	LOW, HYDROGEN, STRONG
7018AC	YES	EP	ALL	LOW	
7024	YES	EP, EN	FLAT HORIZ FILLET	LOW	SMOOTH, EASY, FASTER
Ni-CI	YES	EP	ALL	LOW	CAST IRON
308L	YES	EP	ALL	LOW	STAINLESS
* EP = ELECTRODE POSITIVE (REVERSE POLARITY) * EN = ELECTRODE NEGATIVE (STRAIGHT POLARITY)					
DIAMETERS/AMPERAGES					
1/16	3/32		1/8		5/32
X	40–85		75–125		110–165
20–35	40–85		75–125		110–165
20–45	40–90		80–130		105–180
35–60	80–125		110–165		150–210
30–50	65–100		110–165		150–220
30–50	65–100		110–165		150–220
X	100–145		140–190		180–250
X	50–70		65–85		100–140
X	40–80		75–115		105–160

SKILL DRILL 7-2 Welding Mild Steel with SMAW

1. Prepare the work area and the workpiece to be welded. Use appropriate manufacturers' guidelines to set up the welding equipment and select the proper electrode.

2. Put on all appropriate PPE needed for the welding task.

3. Turn on the welder and place the appropriate electrode into the electrode holder.

4. Scratch or tap the tip of the electrode against the workpiece to start the arc. Maintain the proper electrode angle, movement, and travel speed as the electrode is consumed. Replace consumed electrodes as needed.

5. When the welding bead has been completed, allow it to cool, and then completely remove the slag using a chipping hammer and a wire brush.

6. After completing the welding job, shut down and disconnect the welding equipment and follow all safety precautions related to hot workpiece metal and slag.

SKILL DRILL 7-3 Welding Mild Steel with MIG and TIG

1. Prepare the work area and the workpiece to be welded. Use appropriate manufacturers' guidelines to set up the MIG welding equipment, select the proper electrode wire, and turn on the shielding gas.

2. Put on all appropriate PPE needed for the welding task.

3. Position the electrode tip at the workpiece and press the control switch on the MIG welding gun to start the electric power; the electrode wire feed, and the shielding gas flow.

(Continued)

SKILL DRILL 7-3 Welding Mild Steel with MIG and TIG (Continued)

4. Slowly move the welding gun along the weld joint at the proper travel speed to allow the molten base metal and the filler metal to fill the joint.

5. Use the appropriate manufacturers' guidelines to set up the TIG welding equipment, select the proper tungsten filler metal electrode, and turn on the shielding gas.

6. Depress the TIG welder foot pedal to start an arc at the torch. When the base metal workpiece begins to melt, push the tip of a tungsten filler metal electrode into the arc to allow the molten base metal and the filler metal to fill the joint.

► Air-Arc Gouging

K07004

Air-arc gouging is a process in which metal is removed from a workpiece using the heat from a carbon or graphite electrode arc and a jet of compressed air to blow away the molten metal. Air-arc gouging is commonly referred to by several different names, including air-arc cutting, carbon arc cutting, or air carbon arc cutting (CAC-A). Regardless of the name, however, the process is the same. MORE service technicians might use this process for activities such as cutting off welded-on bucket cutting edges or tooth adapters and removing liners from haul

truck boxes. A few special pieces of equipment are needed to perform air-arc gouging, and the technique used for the process is different from those used in other forms of metal cutting.

Air-Arc Gouging Equipment

Air-arc gouging requires three special pieces of equipment: an electrode cable and torch handle that can be hooked up to a compressed air hose, carbon/graphite gouging electrodes, and a source of compressed air (**FIGURE 7-11**).

The electrode cable has a fitting for connecting the hose from the compressed air source, which is typically an air compressor located nearby (**FIGURE 7-12**). The compressed air is

FIGURE 7-11 Air-arc gouging equipment setup.

FIGURE 7-12 Air-arc gouging electrode cable and torch.

FIGURE 7-13 Air-arc gouging electrodes.

routed to the torch handle, which has small channels through which the air can flow to blow away the molted metal during the air-arc gouging process.

Electrodes used for air-arc gouging are much different from other welding electrodes. Gouging electrodes are available in a variety of sizes, and most of them are copper clad (**FIGURE 7-13**). They are typically a blend of carbon and graphite and are designed to produce the intense heat necessary for air-arc gouging. Technicians should always follow the electrode manufacturer's guidelines when selecting electrodes for air-arc gouging activities.

Air-Arc Gouging Process

Before an air-arc gouging procedure is performed, technicians must make sure that the work area is properly prepared for the intense sparks, noise, and fumes that will occur. The work area must be well ventilated and, if possible, partitioned from the surrounding area. The welding equipment must be properly set up according to the manufacturer's guidelines. The basic steps for an air-arc gouging procedure are as follows:

1. Use the electrode manufacturer's selection guide to select the proper gouging electrode for the job.
2. Connect the electrode cable and the work cable to the welding machine in the proper position according to the manufacturer's recommendations.
3. Set the amperage on the machine according to the electrode manufacturer's guidelines.
4. Connect the work clamp to the base metal workpiece as close to the gouging area as possible.
5. Connect the air hose from the compressed air source to the electrode cable for the gouging torch.
6. Put on all the appropriate PPE required for the job.
7. Turn on the welder and place the appropriate electrode into the electrode holder. Follow the electrode manufacturer's guidelines on how to position the electrode in the holder.

SAFETY TIP

If using a welding helmet that does not have an auto-darkening feature, be sure to lower the front of the welding helmet before initiating an arc to prevent eye damage.

8. Scratch or tap the tip of the gouging electrode against the workpiece to start the arc.
9. Squeeze the torch handle to allow the compressed air to blow away the molted metal from the gouging area.
10. When the electrode is used up, replace it with a new electrode. Continue this process until the gouging job is complete.
11. Turn off the power source and, if applicable, the air compressor. Remove the work clamp from the workpiece.

SAFETY TIP

Remember that the area of the workpiece around the gouge will remain hot for quite a while. Allow ample time for the workpiece to cool before touching it.

► Attitude

A07001

Before setting up and using any type of arc welding equipment, it is critical for MORE service technicians to be thoroughly familiar with the safety regulations and procedures that pertain to the equipment and its use for welding metal. This includes locating and reading any safety-related manuals that may exist on site. Find out where those manuals are normally kept, and take action to obtain the proper manuals for the equipment. If printed manuals are not available for the equipment, try to find electronic versions either from the client or online through the equipment manufacturer's website. It might also be possible to find the appropriate material by searching online. In some cases, it might be necessary to call the equipment manufacturer to get the needed information. Whatever the means, it is important to ensure that the resource material being used matches the equipment and the procedures being performed.

► SMAW Terminology

107001

The terminology associated with the composition and use of SMAW equipment is critical for MORE service technicians. Technicians must be able to accurately use terminology that is common to the trade and understand safety procedures that apply to this work. Federal and state agencies, along with industrial trade groups, have developed standards over the years that technicians can use for source material:

- the Occupational Safety and Health Administration (OSHA) at www.osha.gov, which sets and enforces standards related to safety and equipment
- the National Fire Protection Association (NFPA) at www.nfpa.org, a global nonprofit organization devoted to eliminating death, injury, property, and economic due to fire, electrical, and related hazards
- the American Welding Society (AWS) at www.aws.org, a nonprofit organization with a global mission to advance the science, technology, and application of welding and allied joining and cutting processes—proper procedures for cutting or welding hazardous containers are described in the *American Welding Society (AWS) F4.1, Safe Practices for the Preparation of Containers and Piping for Welding and Cutting*
- the American National Standards Institute (ANSI) at www.ansi.org, an organization that oversees the creation, promulgation, and use of norms and guidelines that impact U.S. businesses—see standard Z49.1 *Safety in Welding, Cutting, and Allied Processes*.

In addition, SMAW equipment manufacturers and magazines covering the welding industry typically have technical information, including glossaries, available on their websites. Technicians working on MORE should exploit all available resources to ensure that they understand the terminology and regulations that apply to the trade.

► SMAW Repair Techniques

107002

An important part of SMAW welding repair involves preparing the metal to be welded. No matter how thin or thick the metal workpieces are, they need to be cleaned and properly positioned before welding begins. Often, welding clamps are needed to hold workpieces in place. In some cases, it may be necessary to tack weld the workpieces to hold them in position for welding or to gap the pieces to allow for expansion and contraction. Thicker metals may have to be beveled to create a suitable joint for the welding bead (**FIGURE 7-14**).

Welding positions, welding types, and welding joints can vary from job to job (**FIGURE 7-15**). Four welding positions that service technicians are likely to use include flat, horizontal, vertical, and overhead. In addition, two common welding types are groove welds and fillet welds, and four common welding joints are butt, corner, tee, and lap.

Groove welds are done on beveled surfaces. This allows the molten base metal and filler metal to fill the prepared joint groove to create a strong connection. Fillet welds, on the other hand, do not require beveling. They are often performed on metal plates that are aligned perpendicular to one another.

FIGURE 7-14 Preparing work pieces for welding.

WELDING TYPES	WELDING JOINTS	WELDING POSITIONS			
		FLAT	HORIZONTAL	VERTICAL	OVERHEAD
GROOVE WELDS	BUTT				
	CORNER				
FILLET WELDS	TEE				
	LAP				

FIGURE 7-15 Welding positions, types, and joints.

Wrap-Up

Ready for Review

- ▶ Shielded metal arc welding (SMAW), or stick welding, is the most commonly used form of arc welding.
- ▶ Stick welding uses the intense heat from an electric arc created between a base metal workpiece and the tip of a filler metal electrode (welding rod) to melt the metals so that they fuse together through coalescence to form a strong welded bond.
- ▶ Stick welding is a popular form of arc welding because the equipment is relatively simple and inexpensive; it can be used on most common metals and alloys; it is generally easy to learn; the filler metal electrodes are widely available and have a flux coating that protects against oxidation; and the equipment is portable, which makes it a good choice for field service applications and limited access areas.
- ▶ The main components of a typical SMAW system include the welding machine, or power source, and its internal components; an electrode cable with an electrode stick holder, a work cable with a work clamp, a power supply cable that plugs into an electric outlet, an on/off power switch, an AC/DC output selector, and an amperage selector.
- ▶ A stick welding machine is essentially a step-down transformer that converts high-voltage, low-current AC power from a wall outlet (or engine) to a lower-voltage, higher-current AC or DC output.
- ▶ Any stick welder that provides DC output power includes a rectifier or some other means to convert the AC input power to a DC output.
- ▶ The AC/DC output selector on a stick welder allows a technician to select the form of output power, while the amperage selector allows the welder to choose the amount of current needed for the welding operation.
- ▶ A typical stick welder can convert AC input power of 220V at 50 amps to a DC output of 25V at 125 amps.
- ▶ DC is the most common current used for stick welding because it flows in only one direction and results in easier arc starting and less sticking and spatter.
- ▶ An SMAW machine provides a constant current output, which means that the output current that accounts for the intense heat at the arc remains relatively constant even when there are variations in the welding conditions—such as when a welding technician varies the distance, or length, of the arc.
- ▶ In SMAW, connecting the electrode cable to the positive terminal of the power source and the work cable to the negative terminal sets up a direct current electrode positive (DCEP), or a reverse polarity, connection, which is the most commonly used connection in stick welding.
- ▶ Electrode sizes for SMAW range from 1/16-inch (1.6 mm) to 3/8 inch (9.5 mm), and the American Welding Society (AWS) provides a standard electrode classification system for service technicians to use when selecting the proper electrode.
- ▶ There are many types and sizes of welding clamps that can be used to hold base metal workpieces in place for welding.

- ▶ Slag that forms on a weld bead must be completely removed before another bead can be laid on top of the previous bead. Slag can be removed using a chipping hammer and a wire brush.
- ▶ Gas metal arc welding (GMAW), or metal inert gas (MIG) welding, requires the use of a shielding gas to protect the weld from oxidation and contaminants in the surrounding air.
- ▶ The three most commonly used gases in MIG welding are argon, carbon dioxide, and helium—or some mixture of them.
- ▶ MIG welding equipment includes a welding machine, or power source; a shielding gas supply; an electrode wire feed reel, or spool; electrode wire; a welding gun; and a work return connection.
- ▶ A control switch on a MIG welding gun starts the electric power, the electrode wire feed, and the shielding gas flow through a liner to the tip of the welding gun. The arc that is created melts the base metal workpiece and the electrode wire to form a molten weld pool where the metals coalesce to form a strong weld.
- ▶ Most MIG electrode wires are one of four sizes: 0.024 inch (0.6 mm), 0.030 inch (0.8 mm), 0.035 inch (0.9 mm), or 0.045 inch (1.2 mm).
- ▶ One of the most common electrode wire types used for general purpose MIG welding of mild steel is ER70S-6.
- ▶ Gas tungsten arc welding (GTAW), or tungsten inert gas (TIG) welding, is most often used to weld thin pieces of metal such as stainless steel or aluminum.
- ▶ TIG welding uses a non-consumable tungsten electrode to produce the electrical arc needed for welding.
- ▶ The TIG electrode heats the base metal workpiece while a separate consumable tungsten filler rod is added to the weld puddle. An inert shielding gas is used to prevent oxidation and prevent impurities at the weld.
- ▶ The main components of a typical TIG welding outfit include a power source, a shielding gas cylinder with a regulator and valves, a coolant system (optional), a torch, a work cable and work clamp, and a foot-operated remote control.
- ▶ Technicians should always wear appropriate PPE when welding with any type of arc welding equipment.
- ▶ Breathing masks or respirators may be required when welding materials that can produce toxic fumes when heated.
- ▶ To minimize the risk of fire and explosion, technicians should always inspect and prepare the machinery or equipment to be worked on, as well as the work area and its surroundings before using arc welding equipment.
- ▶ If the work area is a confined space or if it requires a hot-work permit or a fire watch, follow all requirements and procedures for the site to avoid serious injuries and penalties.
- ▶ Make sure that the work area is properly ventilated by using fans, exhaust hoods, or ventilated booths.
- ▶ Mild steel is basically a low-carbon steel (0.25% or less carbon) that is used in countless everyday applications.
- ▶ An E6010 is a good general purpose SMAW electrode for most steel repairs.

- ▶ Air-arc gouging is a process in which metal is removed from a workpiece using the heat from a carbon or graphite electrode arc and a jet of compressed air to blow away the molten metal.
- ▶ Air-arc gouging is commonly referred to by several different names, including air-arc cutting, carbon arc cutting, or air carbon arc cutting (CAC-A).
- ▶ MORE service technicians might use air-arc gouging for cutting off welded-on bucket cutting edges or tooth adapters and for removing liners from haul truck boxes.

Key Terms

coalescence The fusing together of two or more metals that occurs when the metals are heated to a point of liquefaction and, after cooling, are bonded together to form one continuous solid.

confined space An enclosed area that has limited space and accessibility and requires special safety procedures for entering, working, and exiting.

constant current The ability of a system to maintain a consistent current output even when there are voltage variations in the load.

Direct Current Electrode Positive (DCEP) The flow through an electrical circuit that is formed when an electrode cable is connected to the positive terminal of a power source and the work cable is connected to the negative terminal of the power source; also referred to as a reverse polarity connection.

electrical polarity The direction of current flow in an electrical circuit based on the fact that current flows from the positive pole, or terminal, to the negative pole.

power source A component in an arc welding system that converts AC input power into an AC or DC output at the appropriate voltage and current levels needed for the welding task.

rectifier A device that converts alternating current (AC) to direct current (DC).

reverse polarity The flow through an electrical circuit that is formed when an electrode cable is connected to the positive terminal of a power source and the work cable is connected to the negative terminal of the power source; also referred to as a direct current electrode positive (DCEP) connection.

slag Oxidized and molten metal waste that is left over from welding operations.

spats A type of PPE, often made of leather, worn over the laces and tongue of work boots to protect workers from hot metal.

step-down transformer A component that converts high-voltage, low-current AC power from a wall outlet (or engine) to a lower-voltage, higher-current AC or DC output.

Review Questions

1. In most SMAW applications, the welding machine power source converts high-voltage, low-current AC power to a _____.
 - a. higher-voltage, lower-amperage AC output
 - b. constant-voltage, constant-current output

- c. lower-voltage, lower-current AC/DC output
 - d. lower-voltage, higher-current DC output
2. The amperage selector on a stick welding machine allows the welder to choose _____.
 - a. the type of source power being provided to the welder
 - b. the amount of current needed for the welding operation
 - c. the speed at which the electrode wire is fed to the torch
 - d. the voltage level flowing to the work cable and clamp
 3. Connecting the electrode cable to the positive terminal of an SMAW power source and the work cable to the negative terminal of the power source sets up a(n) _____.
 - a. direct current electrode negative (DCEN) connection
 - b. alternating current inverse polarity (ACIP) connection
 - c. direct current electrode positive (DCEP) connection
 - d. alternating current straight polarity (ACSP) connection
 4. In the American Welding Society (AWS) standard electrode classification system, the first two numbers in a stick welding electrode name indicate _____.
 - a. the tensile strength of the welded joint
 - b. the acceptable welding position(s) for the electrode
 - c. the amount of penetration provided
 - d. the type of flux coating material on the electrode
 5. The three most commonly used gases in MIG welding are _____.
 - a. nitrogen, oxygen, and helium
 - b. argon, carbon dioxide, and helium
 - c. carbon dioxide, acetylene, and argon
 - d. helium, hydrogen, and carbon dioxide
 6. Which arc welding process is most likely to require a filler metal electrode rod, a foot-operated remote control, and a coolant system?
 - a. Shielded metal arc welding (SMAW)
 - b. Gas metal arc welding (GMAW)
 - c. Metal inert gas (MIG) welding
 - d. Gas tungsten arc welding (GTAW)
 7. If a technician is going to be exposed to toxic fumes for a long period of time during an arc welding procedure, the technician should wear a _____.
 - a. full-face, supplied-air respirator (SAR)
 - b. high-efficiency particulate arresting (HEPA) filter
 - c. pure oxygen supply mask (POSM)
 - d. dampened charcoal canister mask (DCCM)
 8. During arc welding, where should the work cable clamp be connected?
 - a. At least 12 inches (305 mm) from the welding area of the workpiece.
 - b. To any dry wooden object in the vicinity of the welding area.
 - c. As close as possible to the welding area of the workpiece.
 - d. To a grounding buckle on the welder's leather apron.
 9. How often should slag be removed during stick welding activities?
 - a. SMAW does not create slag.
 - b. Slag should be removed after every bead is laid.
 - c. Never. Slag protects the weld from oxidation.
 - d. All slag can be removed at once when the welding process ends.

10. What typically flows through the torch handle during an air carbon arc cutting process to remove molten metal?
 - a. liquid coolant
 - b. graphite powder
 - c. carbon fibers
 - d. compressed air

ASE Technician A/Technician B Style Questions

1. Technician A says the heat from a stick welder arc melts the workpiece metal and the filler metal electrode so that they fuse together through coalescence. Technician B says the metals fuse together through adherence. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says the filler metal electrodes used in stick welding require additional flux or a shielding gas. Technician B says SMAW electrodes already have a flux coating. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says a stick welding machine is essentially a step-up transformer. Technician B says the machine converts low-voltage, high-current AC power to a higher-voltage, lower-current AC or DC output. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
4. Technician A says a stick welder that provides DC output power needs a rectifier or similar means to convert the AC input power to a DC output. Technician B says the only component needed to make the conversion is the electrode arrestor. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says the most commonly used circuit connection in SMAW is direct current electrode positive (DCEP). Technician B says the most commonly used circuit connection is reverse polarity. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
6. Technician A says a type of arc welding that uses a shielding gas to protect an electrode wire that is continuously fed into the weld is called tungsten inert gas (TIG) welding.

Technician B says that type of arc welding is called gas tungsten arc welding (GTAW). Who is correct?

- a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B
- 7.** Technician A says ANSI and AWS guidelines for arc welding recommend the darkest lens available (shade 6) for eye protection. Technician B says ANSI and AWS guidelines recommend shade 10 to shade 14. Who is correct?
- a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B
- 8.** Technician A says the best way to ventilate a work area before and during a stick welding procedure is to use fans or exhaust hoods. Technician B says the way to purify and ventilate a work area is to release a long burst of oxygen from the SMAW cylinder. Who is correct?
- a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B

- 9.** Technician A says mild steel is easily welded using SMAW because the steel is not all that hard or brittle. Technician B says an E6010 electrode is suitable for most general mild steel repairs using SMAW. Who is correct?

- a.** Technician A
- b.** Technician B
- c.** Both Technician A and Technician B
- d.** Neither Technician A nor Technician B

- 10.** Technician A says you have to use an inert gas, such as oxygen, to remove molten metal during an air-arc gouging process. Technician B says you should use compressed air. Who is correct?

- a.** Technician A
- b.** Technician B
- c.** Both Technician A and Technician B
- d.** Neither Technician A nor Technician B

CHAPTER 8

Principles of Hoisting, Rigging, and Slings

Knowledge Objectives

After reading this chapter, you will be able to:

- **K08001** Identify and describe the purposes, types, functions, and applications of lifting, rigging and blocking equipment.
- **K08002** Describe wire rope applications.
- **K08003** Discuss winch design, operation, and troubleshooting procedures.
- **K08004** Explain towing, transporting, and coasting precautions.
- **K08005** Describe proper lifting techniques and equipment according to occupational health and safety standards.

Skills Objectives

After reading this chapter, you will be able to:

- **S08001** Demonstrate manual lifting procedures using correct body mechanics.
- **S08002** Demonstrate inspection, testing, and operating procedures for lifting rigging and blocking equipment following manufacturers' recommended procedures and government regulations.

Attitude Objectives

After reading this chapter, you will be able to:

- **A08001** Locate and follow appropriate safety procedures when using lift equipment.

Industry/Accreditation

After reading this chapter, you will be able to:

- **I08001** Recommend equipment for lifting components and equipment.

► Introduction

This chapter introduces the mobile off-road equipment (MORE) technician to the principles of lifting, support using blocking and cribbing, and towing operations. We also specifically review the types of equipment used in hoisting, rigging, winching, towing, and blocking. This consists of a brief overview of the equipment, techniques, procedures, and safety-related information on these topics. The safe and proper procedures and use of many types of equipment used for lifting, rigging, hoisting, supporting, and towing requires specialized training and experience (**FIGURE 8-1**). This chapter is not a substitute for the proper training and experience required to safely and correctly operate this type of equipment.

SAFETY TIP

Lifting heavy objects is no joke! The larger and heavier an item is, the more inherent danger there is when undertaking a lifting operation. Always take the time to ensure you are properly trained and qualified,

FIGURE 8-1 The operation and use of most types of lifting, hoisting, towing, rigging, and blocking equipment and devices requires specialized training and experience. Failure to be properly trained and experienced when operating these types of equipment and devices may result in serious equipment damage, injury, and death to yourself and others!

FIGURE 8-2 The parts, components, and assemblies of MORE can weigh thousands of pounds, or hundreds of kilograms, requiring the use of specialized lifting equipment.

and follow safe practices when operating lifting, hoisting, rigging, and blocking equipment and devices.

As mentioned previously, specialized training and instruction is required for most types of specialized heavy lifting, towing, and supporting equipment and devices. Because of this, we only briefly review self-powered equipment used for lifting, towing, and supporting heavy objects. The bulk of the information here focuses on the non-self-powered devices and equipment used for lifting and supporting heavy objects inside the MORE shop.

Typically, MORE is large, heavy, and bulky. As such lifting, towing, and supporting many MORE parts and components require specialized heavy-duty equipment and devices. Many of these parts and components can weigh thousands of pounds (or hundreds of kilograms), or even more (**FIGURE 8-2**).

As we go through the different objectives in this chapter, we will review the following:

- Lifting equipment and devices (hoisting, rigging, slings, wire rope/cables, and winches)

You Are the Mobile Off-Road Equipment Technician

You are replacing the dump bed on a 200-ton capacity Caterpillar 789D Mining Truck. You will be utilizing a certified and properly trained team to perform this lifting event and to operate a 100-ton capacity gantry in your shop, for removal. Once removed, the dump bed will have to be moved outside the shop and placed on a concrete pad to await reconditioning.

1. What are the critical weights and capacities that should be researched before planning this major lift event?
2. How can you determine if the proper lifting equipment and capacity are utilized?
3. How can you determine what lifting points to use on the dump bed?
4. How many lifting points should you use?
5. How do you determine which component is the limiting load factor in the operation?
6. When the dump bed is removed, should it rest directly on the ground?
7. How should the lift bed be supported to prevent damage to the concrete pad on the ground?

- Blocking devices (blocking and cribbing)
- Towing equipment and devices
- Proper lifting techniques for human manual lifting

To start, let's establish some definitions of the types of procedures and devices we are talking about. **Lifting equipment**, also known as lifting gear, is any equipment or devices used to lift a load vertically. This can include jacks, a block and tackle, vacuum lift, hydraulic lift, hoist, gantries, windlasses, cranes, forklifts, slings or lifting harnesses, rigging, wire rope/cables, and any other items used to lift a load vertically. Here, we refer to all types of equipment and devices used for lifting a load as lifting equipment.

In this chapter, we refer to all equipment and devices used to support a load in a stationary position as **blocking devices**, also referred to as **blocking** and **cribbing**. This includes blocking, cribbing, jack stands, timbers, dunnage, and any other devices or equipment designed to support a load in a stationary position.

Towing equipment and devices are any equipment or devices used to pull, or tow, a load horizontally. This includes towing ropes, cables, linkage devices, and any other devices used in the towing process.

In this chapter, we refer to manual lifting as lifting done by a person without the aid of mechanical devices. This may include a single person or multiple people. We also discuss here some safety equipment used in manual lifting.

History of Lifting, Blocking, and Towing Equipment

The simplest lifting device is the lever. Some of the earliest written accounts and drawings of a mechanical lever were from Archimedes in the 3rd century BCE. Although it is certain that levers and lifting devices have been in use for thousands of years prior to Archimedes, his writings and drawings are the earliest proof still existing of the mathematic principles of the lever. Although the actual devices and equipment used for lifting, blocking, and towing from ancient times may not survive today, signs of their use are clearly evident (**FIGURE 8-3**).

The laws of physics have not changed from ancient times until today. Heavy items still require mechanical lifting devices, proper blocking equipment to support their weight, and towing equipment to pull them horizontally.

► Purpose, Usage, and Types of Lifting and Blocking Equipment and Devices

K08001, S08001, S08002, A08001, I08001

Many different types of lifting devices are used in the MORE field. In most motive power applications, lifting devices are used on an occasional basis, but in heavy equipment they are essential, even to some tasks that would otherwise be considered relatively simple. With MORE, even removing the wheels of a machine can require extensive lifting equipment, as their wheel components can weigh thousands of pounds. The MORE technician must be able to use a variety of lifting equipment throughout the workday, from simply muscle power to operating large gantry cranes capable of lifting several hundred tons, and he or she must do so safely and with confidence. Next, we discuss some of the more common lifting systems.

Manual Lifting

The most elementary piece of lifting equipment is the muscle. But human muscles can be easily injured, affecting your ability to work. You can prevent many debilitating back and knee injuries by using proper lifting techniques. When bending down to lift an object, for example, always bend at the knees before attempting to lift. Never bend from the waist, which is the surest way to strain your back or, in a worst-case scenario, rupture a disc in your back. Place your feet on either side of the object you want to lift, and point them in the direction you wish to travel. If an item is too awkward or large for you to lift on your own, ask someone to help you lift it. To use correct manual lifting techniques, see the steps outlined in **SKILL DRILL 8-1**.

© Dorling Kindersley/Getty Images.

FIGURE 8-3 A. A replica lifting device from ancient Roman times. **B.** Ancient Egyptians using towing ropes and rollers to pull heavy stone blocks. The principles of lifting, blocking, and towing remain the same.

SKILL DRILL 8-1 Correct Manual Lifting Techniques

1. Plan your movement—what your path of travel while carrying the object will be.
2. Decide whether your item will require one person or two persons to carry.
3. Determine where the center of gravity of the object is; place the center of gravity closest to your body when lifting.
4. Check to see whether the item has handles; it is usually easier to use handles to lift an item.
5. Place your feet shoulder-width apart in front of the item.
6. Squat down, bending at the knees and hips only to grasp the item.
7. Look straight ahead, keep your back straight, chest out, and shoulders back.
8. Slowly lift by straightening your hips and knees. Keep your back straight and don't twist.
9. Hold the object as close as possible to your body, and carry at belly button level.
10. Set the load down carefully, squatting with your knees and hips while keeping your back as straight as possible.

Lifting Equipment and Devices

As stated in the introduction, lifting equipment, also known as lifting gear, is any equipment or devices used to lift a load vertically. This can include jacks, a block and tackle, vacuum lift, hydraulic lift, hoist, gantries, windlasses, cranes, forklifts, slings or lifting harnesses, rigging, wire rope/cables, and any other items used to lift a load vertically. Another word we need to define is **hoisting**. Hoisting is the action of lifting a load using cables or ropes. Although a load may be referred to as being “hoisted,” when it is lifted vertically using cables or ropes, if the same load is lifted using hydraulic jacks (pushed up vertically), it is being lifted. For the purposes of this chapter, **rigging/rigging gear** are all the components used to attach the mechanical hoisting equipment to the load being lifted. This can include rope, wire rope/cables, slings, shackles, eyebolts, eye nuts, links, rings, turnbuckles, rigging hooks, compression hardware, rigging blocks, load-indicating devices, and precision load positioners. A person who specializes in the lifting and moving of heavy objects is called a **rigger**. Because riggers undergo a large amount of special training and education to safely and properly lift and support large and heavy items, they may be required for these critical jobs. The MORE technician can conduct lifting or supporting operations for smaller jobs when a rigger is not required. When in doubt about the safe and proper planning, application, and use of lifting and supporting equipment and procedures, refer to the machines service information or consult a certified rigger.

► TECHNICIAN TIP

As a MORE technician, sometimes you need to have knowledge and responsibilities that may normally be handled by a dedicated specialist. Before undertaking a task outside of your normal knowledge and capabilities, ask yourself whether this operation may require a certified specialist or special training—and whether you are confident you can safely perform the task. Some lifting, towing, and blocking equipment and procedures may not require a special certification or a dedicated specialist to perform, but others do. Know your limits, and if in doubt, stop. Consult the equipment manufacturer's manual and industry or government regulations. It is better to take your time to ensure all aspects of a heavy lift are conducted properly by properly trained personnel. Failure to use proper techniques, procedures, equipment, and trained personnel can result in equipment damage, serious injury, or even death.

Selecting Appropriate Lifting Equipment

You may end up using many different types of lifting equipment in a shop. Lifting equipment is designed to lift and securely hold loads. Some examples of lifting equipment include vehicle hoists, floor jacks, jack or jack stands, engine and component hoists, mobile gantries, chains, slings, and shackles. Each piece of lifting equipment has a maximum weight it can support. The maximum operating capacity is usually expressed as the **safe working load (SWL)**. For example, if the SWL is 1 ton, the equipment can safely lift up to 2,000 pounds (907 kg). When using lifting equipment, never exceed its capacity, and always maintain some reserve capacity as an extra safety margin. In addition, you should use each piece of lifting equipment for its designed purpose only. For example, use a vehicle hoist only to lift equipment within its capacity. Using lifting equipment incorrectly may lead to equipment failure that can cause serious injury and damage.

The Safe Use of Lifting Equipment

In addition to double-checking safe working loads and using equipment only for its intended purpose, technicians can take several other steps to ensure a safe operating environment. These include testing and test certification. Requirements can vary by country and your local area, so be sure to check with your supervisor if you have any questions.

SAFETY TIP

Know which lifting equipment in your shop requires special training and/or certification. If you do not have the special training and certification to operate a piece of lifting equipment, *do not* operate it. Find a qualified person to operate the equipment and perform the task you need completed. These items require special training and certification for a reason; they can be extremely complex to operate and present a huge potential safety hazard.

► TECHNICIAN TIP

When using multiple pieces of lifting equipment, the SWL (safe working load) is limited to the lowest rated piece of equipment. Remember, “A chain is only as strong as its weakest link.” Consider the rigging such as the chains, cables, ropes, fittings, rings, the equipment tie-down

points, and the lifting equipment such as the hoist or crane you are using on a heavy lift. The lifting equipment's capacity is limited by the strength of the weakest single component. For example, a 5-ton chain with a 3-ton D-shackle has a maximum lifting capacity of 3 tons or less.

► TECHNICIAN TIP

Manufacturers supply operating information for lifting equipment, including the equipment's SWL. Check the lifting equipment's SWL, and compare it with the weight of the object or vehicle you intend to lift. Never exceed the SWL.

Testing Lifting Equipment

Lifting equipment should be periodically checked and tested to make sure it is safe, in accordance with local regulatory requirements. The testing should be recorded for each piece of lifting equipment, and the equipment should be clearly labeled with a sticker affixed to it that includes its inspection date and SWL. Inspections should identify any damage, such as cracks, dents, marks, cuts, and abrasions, which could prevent the lifting equipment from performing as designed. Refer to the manufacturer's manual to find out how often maintenance inspections are recommended. The time frame is usually every 12 months in the case of hoists and lifts, but may be longer for lifting equipment such as chains and slings. Always check local regulations to determine the requirements for periodic testing of lifting equipment.

Checking the Test Certificate

In most countries, lifting equipment is subject to statutory testing and certification. If this is the case where you work, the **test certificate** should be attached to or displayed near the lifting equipment (**FIGURE 8-4**).

Before using a piece of lifting equipment, make sure the most recent inspection recorded on the test certificate is within the prescribed time limit. If it is not, the test certificate has expired, and you should notify your supervisor.

FIGURE 8-4 Compliance testing tags contain details of when the last test was done and when the next test is due.

Selecting Appropriate Lift Points

When dealing with lifting heavy objects, it is critical to lift the object using solid and secure lift points with enough capacity to lift the item without damage. In many cases, a lifting device is used that pushes the item up vertically, by using a jack between the ground and a suitable lift point under the equipment (**FIGURE 8-5**).

SAFETY TIP

Failure to utilize proper lift points may result in equipment damage or injury. Whether you are lifting from below using a jack, or from above using a hoist, ensure you use designated and proper lift points when available. Lifting a heavy item can place a lot of strain into a very small area, possibly resulting in failure of the lifting point. In the absence of a manufacturer's designated lifting point, utilize the strongest area available.

In these cases, look for a designated lift point first. If none is available, use the strongest part of the item. Other critical factors in selecting a good lifting point are looking for ones that will allow good positioning with the item's center of balance, and for one that has a stable part that will not move or slip on the jack.

Just as important as ensuring that the lifting points are strong enough to support the lift is making sure that the correct lifting point positioning is used. In explaining this, we need to define a few terms. The **center of gravity (CG)**, also called the center of balance, of an object is the point, or position, at which the item's weight is evenly dispersed, and all sides are in balance. If the item were to be supported in a direct vertical axis from the center of gravity, it would balance perfectly. As the center of gravity is a position, it has units of length; inches, feet, meters, centimeters. The center of gravity of an object can be described as the distance from an arbitrary reference point on the item, to the center of gravity. The arbitrary reference point from where the center of gravity is measured is called the **reference datum line (RDL)**. For instance, the manufacturer of a certain piece of heavy equipment may describe the item's center of gravity as being 200 inches

FIGURE 8-5 Always identify and use the correct lifting points when lifting a heavy item. Consult the manufacturer's maintenance and repair manual if lifting points are not readily identified.

from the item's front end, where the manufacturer may define the "front end" as the point where the front of the machine protrudes the most, at a height of 24 inches above ground level. Where the reference datum line is on an item does not matter, so long as it is specifically defined and does not change.

The further away the item is supported from the vertical axis of the center of gravity, the more it has a tendency to rotate. The tendency of an item to rotate about a pivot is called torque.

Take the case where you are lifting an item by jacking from underneath. If the jack is placed at a lifting point not in the same vertical axis of the center of gravity, the item will tend to rotate as it is being lifted. In many cases, this is not desirable and creates an unstable condition. However, if the jack is placed at a lifting point that is in the same vertical axis of the item's center of gravity, it will lift straight up and not rotate. Therefore, it is important to know where the item's center of gravity is, before lifting. An item that is lifted by utilizing a poorly positioned lifting point can become unstable and fall.

The same principle applies to lifting an item from above by hoisting. If a single point chain or rigging is used, it must

be placed in the same vertical axis as the item's center of gravity. If it is not, the item will rotate until the center of gravity of the item is in the same vertical axis as the lifting hook (FIGURE 8-6).

When lifting an entire piece of equipment, many times the center of gravity will be posted on the equipment itself or on a data plate. The center of gravity may also be listed in the manufacturer's technical manual. When the center of gravity is included on a data plate or in a technical manual, it is defined as a distance from the manufacturer's RDL. In many cases, the MORE technician will be utilizing lifting equipment to lift heavy parts and subcomponents of a larger piece of equipment. In these instances, the item's center of gravity is not predetermined, and MORE technicians must use their own best judgment on whether a more in-depth analysis must be done before undertaking the lift. Certain very large or heavy items are considered to entail a critical lift, which requires a specialist to perform. These types of lifts are not covered in this chapter. However, there are many heavy lifts that the MORE technician can do in the shop or field that do not require special certifications.

Effect of Center of Gravity on Lift

FIGURE 8-6 The position of the lifted item's center of gravity with respect to the lifting hook and lifting points is critical. Poor positioning will cause the load to shift and may result in equipment damage and injury.

In these cases, safety is paramount, especially where the item's CG is not known and therefore the load may be subject to shifting. Keep these criteria in mind when selecting your lifting points:

- When available, use the manufacturer's dedicated lift points.
- Ensure that the lifting points capacity is known and will not be exceeded.
- When lifting an item from below by jacking, use a lift point that is *below* the item's center of gravity.
- When lifting an item from above by hoisting, use a lift point that is *above* the item's center of gravity.
- When lifting using a single lift point, use a lift point in the same vertical axis as the item's center of gravity.
- When hoisting using two lift points, place them symmetrically the same distance apart from the item's center of gravity.
- When lifting an item by hoisting, keep the lifting hook in the same vertical axis as the item's center of gravity.

Types of Lifting and Moving Equipment

Once you have verified that a piece of equipment is safe to use, you can get to work. You will use your shop's lifting equipment not only to raise heavy components but also to move and lower pieces into place as well. Which equipment you use depends on a part's size, weight, and type, as well as the job you intend to perform. This section looks at several different types of lifting and moving equipment.

Chain Blocks and Mobile Gantry Cranes Chain blocks and mobile gantry cranes are often used together to lift larger components inside heavy equipment shops. Chain blocks can be attached to, and hang from, mobile gantries. Chain blocks lift parts, and mobile gantries move wherever the work needs to be done.

Chain blocks have a safety latch and hook fittings that attach to lifting points on a component. Once attached to a load, the chain block lifts large components when the technician pulls the chain through a rotating wheel. Mobile gantries can either be wheeled into place on a floor or are mounted on tracks near the roof of the shop and operated with hand controls that move the gantry into position and lower the chain block with a hook (FIGURE 8-7).

Both lifting devices relieve the technician of having to exert a lot of effort to remove heavy components and lower them into an area where they can be serviced or replaced. Carefully check the lifting hooks on these devices before use, to make sure the end of the hook hasn't opened beyond the standard limit. Inspect chains for any mud or grit, and examine safety latches to be sure they are working properly.

Slings and Shackles Slings are another type of lifting equipment. Technicians use them to lift and lower many things in the shop. For example, a transmission, engine, or differential can be lifted using these devices (FIGURE 8-8).

They can be made from strong webbing material, wire rope, or chain. Webbed slings have an eye at each end for the

FIGURE 8-7 Gantry crane used for heavy lifting.

FIGURE 8-8 Chain-type slings and other heavy lifting components in a shop.

connection of shackles (discussed later in this section) to attach loads. Wire rope and chain slings may have any number of different fittings for different applications. Regardless of the sling type and its fittings, each will have a maximum working load that you cannot exceed. As with all lifting equipment, you must test slings regularly to ensure they are safe to use. If you suspect that any piece of lifting equipment is damaged, do not use it. Have it tested before placing it into service. Webbed slings are usually flat in appearance and made from strong synthetic materials such as polyester. Synthetic slings can be more susceptible to cutting or abrasive damage than harder materials, such as chains or wire, and should be checked before each use to ensure they are not damaged. Web slings are available in a variety of lifting capacities for different lifting tasks. When using synthetic slings, always ensure they are protected from sharp corners, which may damage the slings and reduce lifting capacity. Wire rope slings are made from many strands of fine wire and a core. The size, number, and arrangement of the wires determine the sling's lifting capacity. Wire rope slings are less susceptible to abrasion and cutting than synthetic slings, but

FIGURE 8-9 Chains can have many different types of fittings at either end.

always check them for any damage, such as kinks and broken or cut wires, as these will reduce their lifting capacity. Chains are made from hardened steel and are not as susceptible to damage as synthetic or wire rope slings. Chains can have several different types of fittings attached to the ends, such as eyes, shackles, and hooks (**FIGURE 8-9**).

Chains, like all lifting equipment, should be checked for damage before being used and regularly tested and tagged. Shackles are attached to slings and chains to use as connectors between a component and various applications, such as lifting equipment. See **FIGURE 8-10** for an example.

In lifting equipment, shackles are secured with a pin through the bottom of the shackle. Secure D-shackles, a common type of shackle, with a piece of wire through the shackle's eye, to lock the pin and prevent it from working loose. The same applies to bow shackles. As with all lifting equipment, inspect shackles to make sure they are in good condition and free from dirt and grime.

Jacks and Jack Stands Jacks and **jack stands** are used every day in heavy equipment shops to safely lift and support equipment. Although a jack is a lifting device, and a jack stand is a supporting device, we speak about both here as they are usually used and spoken about together. As with other shop equipment, before use it is important to check jacks and jack stands for safety reasons. If you suspect that they are faulty, *do not use them*. Take them out of service, and have them tested and serviced.

FIGURE 8-10 D-shackles can be used to connect pieces of lifting equipment. Do not use D-shackles with an unknown lifting capacity/rating.

Jacks An equipment jack is a lifting tool that can raise part of an object from the ground prior to removing or replacing components, or raise heavy components into position. Jacks used for lifting heavy-duty equipment operate the same as the jacks you are probably familiar with, to lift vehicles. The only difference is, jacks used to lift heavy equipment are larger and have a greater lifting capacity (**FIGURE 8-11**). Although you can use a jack to raise and support a piece of equipment, you must not use an equipment jack to support the equipment's weight during any task that requires you to get underneath any part of it. For any shop tasks that call for you to crawl under a piece of equipment, only use a jack to raise the equipment so that it can then be lowered onto suitably rated and carefully positioned stable jack stands or blocking.

The three main types of jacks are the **hydraulic jack**, **pneumatic jack**, and **mechanical jack**. Hydraulic and pneumatic jacks are the most common types. They can be mounted on slides or on a wheeled platform. In hydraulic jacks, pressurized oil acts on a piston to provide the lifting action; in pneumatic jacks, compressed air lifts the vehicle; in mechanical jacks, a screw or gears provide the mechanical leverage required for lifting.

Different jacks are available for different purposes:

- **Floor jacks** are a common type of hydraulic jack that is mounted on four wheels, two of which swivel to provide a steering mechanism. The floor jack has a long handle that is used both to operate the jacking mechanism and to move and position the jack. Floor jacks have a low profile, making them suitable to position under vehicles.
- **Bottle jacks** are portable jacks that usually have either a mechanical screw or a hydraulic ram mechanism that rises vertically from the jack's center as you operate the handle. They are relatively inexpensive too automotive and may be provided with vehicles for changing flat tires.

Air jacks use compressed air either to operate a large ram or to inflate an expandable air bag rarely used to lift the vehicle. Often the air jack is fitted to a movable platform with a long handle.

FIGURE 8-11 A jack should only be used to raise part of a piece of equipment enough to install jack stands, blocking, or other stable and proper supporting devices. Never work under a piece of equipment supported only by jacks or other lifting devices.

You use air jacks to lift vehicles as an alternative to floor jacks. Because they require a compressed air supply, air jacks are usually used in the shop rather than for mobile operations. An air bag-type jack can be especially useful in situations where a very low-profile jack is needed; the jack will sit on an uneven surface; or the load to be lifted must be spread out over a larger area of jacking surface.

- *Sliding-bridge jacks* are usually fitted in pairs to four post hoists as an accessory to allow the vehicle to be lifted off the drive-on hoist runways. Operated by a hydraulic mechanism or compressed air, sliding-bridge jacks use a platform mounted to a scissor-action jack to lift the vehicle along the length of the runway, thus making it more convenient to work on wheels and brakes. These types of lifting systems may be found in shops that cater to lighter pieces of more equipment.
- *Transmission jacks* are specialized jacks for lifting and lowering transmissions during removal and installation. Transmission jacks are usually mounted on a floor with wheels and have a large flat plate area on which the transmission rests securely. They are usually operated by a hydraulic mechanism but can also be powered by compressed air.

Jack Stands Jack stands, also known as just stands, are adjustable supports used with jacks. They are designed to support a machine's weight once it has been raised by a jack. They normally come in matched pairs and should always be used as a pair (**FIGURE 8-12**).

Jack stands are mechanical devices, meaning they mechanically lock in place at the height selected. Stands are load rated, so you should only use them for loads less than the rating indicated on the jack stand. They are very dependable if you use them properly.

Always grip jack stands by the sides to move them. Never grip them by the top or the bottom to move them, as they can slip and pinch or injure you. Check that a stand's base is flat on the ground before lowering a machine onto it; otherwise, the stand might tip over, causing the machine to slip off. Once

you have the jack stands positioned correctly, you can lower the machine onto the stands and move the jack out of the way.

SAFETY TIP

For safety's sake, always place the jack stand locking pins into the aligned holes of the jack stand frame and the movable support platform.

Jack stands provide a stable support for a raised machine that is safer than the jack because the machine cannot be accidentally lowered while the stands are in place. Once you are ready to lower a machine that is on stands, you first raise it again with a jack so you can remove the stands. Because lifting devices are also lowering devices, remember that it's unsafe to work underneath a machine that is supported only by a jack, because it could give way or be accidentally lowered. Never use stands for a job for which they are not recommended.

SAFETY TIP

Never support a machine on anything other than jack stands. Do not use wood or steel blocks to support a machine in the shop; the blocks might slide or split under the machine's weight. Do not use bricks or concrete blocks to support a machine either; they will crumble under the weight.

Using Vehicle Jacks and Jack Stands The weight of the machine you want to lift will determine the size of the jack you use. Always check the capacity of the jack before lifting a machine. If the end of the machine is heavier than usual, or if the machine is loaded, you need to use a jack with a larger lifting capacity. Make sure the stands are in good condition and that their size and capacity are adequate before you use them to support the machine. If they are cracked or bent, they will not support the machine safely. Always use matched pairs of jack stands. To lift and secure a machine with a floor jack and stands, follow the guidelines in **SKILL DRILL 8-2**.

Vehicle Hoists A **vehicle hoist** raises a whole vehicle off the ground so that a technician can easily work on the vehicle's underside. Although this type of lifting system is rarely encountered in a typical MORE shop, it is mentioned here to explain its use should you come across it in shops that also work on equipment transportation vehicles. The vehicle hoist is also useful for raising a vehicle to a height that eliminates the need for the technician to bend down. For example, when changing wheels, you can raise the vehicle to waist height to avoid excessive bending. Vehicle hoists are available in several different designs. They also come in a range of sizes and configurations to meet a shop's needs. For instance, some vehicle hoists are mobile, and others are designed for use where the ceiling height is limited. You can electronically link together some vehicle hoists to use on longer vehicles, such as trucks and buses.

Hydraulic Hoist One type of vehicle hoist, the **hydraulic hoist**, is very easy to use with most vehicles. You drive a vehicle onto a platform so that the wheels rest on two long, narrow platforms, one on each side of the vehicle (**FIGURE 8-13**). Next,

FIGURE 8-12 Always use jack stands in matched pairs.

SKILL DRILL 8-2 Lifting and Securing a Machine with a Floor Jack and Stands

1. Position the machine on a flat, solid surface. Put the equipment into Neutral or Park, and set the emergency or hand brake. If applicable place wheel chocks in front of and behind the wheels that are not going to be raised off the ground.
2. Select two stands of the same type, suitable for the equipment's weight. Place one stand on each side of the vehicle at the same point, and adjust them so that they are both the same height.
3. Roll the equipment jack under the vehicle, and position the lifting pad correctly under the frame, crossmember, or specified jacking point. Turn the jack handle clockwise, and begin pumping the handle up and down until the lifting pad touches and begins to lift the equipment. If jacking on the chassis frame, always use a

wooden block or similar device between the jack and the frame to protect the frame from gouges.

4. Once the wheels or tracks lift off the floor, stop and check the placement of the lifting pad under the machine to make sure there is no danger of slipping. Double-check the position of the wheel chocks to make sure they have not moved. If the machine is stable, continue lifting it until it is at the height at which you can safely work under it.
5. Slide the two stands underneath the machine, and position them to support the machine's weight. Slowly turn the jack handle counterclockwise to open the release valve, and gently lower the machine onto the stands. When the equipment has settled onto the stands, lower the jack completely, and remove it from under the equipment. Gently push the equipment sideways to make sure it is secure. Repeat this process to lift the other end of the machine.
6. When the repairs are complete, use the jack to raise the equipment off the stands. Slide the stands from under the machine. Make sure no one goes under the machine or puts any body parts under the it, as the jack could fail or slip.
7. Slowly turn the jack handle counterclockwise to gently lower the equipment to the ground. Return the jack, stands, and wheel chocks to their storage area before you continue working on the equipment.

FIGURE 8-13 This type of hydraulic hoist is rarely seen in shops that work exclusively on MORE.

the platforms are raised, taking the vehicle with them. The vehicle's underside is then accessible to the technician. Because the vehicle rests on its wheels on the hoist, you can't remove the wheels unless the hoist is fitted with sliding-bridge jacks.

Portable Lifting Hoists Another type of vehicle hoists is **portable lifting hoists**, or *portalift mobile hoists* as they are sometimes referred to. These offer a lifting system that is simple to operate and allow complete underbody access for maintenance and repair. Portalift hoists again are not very common in shops that work on heavy equipment. Portable lifting hoists do, however, provide shop flexibility as they are fully portable and

can be easily moved to any area of a standard shop floor. You can raise or lower the hoist posts individually, in pairs, or all together. When used as a group, they are coupled together with cables to ensure that they operate in sync with one another, and the vehicle is raised equally on each leg of the hoist (**FIGURE 8-14**).

Many types have cable hangers allowing you to keep your cables off the shop floor. The vehicle being worked on can always be put in the best possible position to suit the type of work being done. This can save time and provides the correct working condition for the technician. The hoists can be set at the best height for the task being performed and for the individual technician doing the job. Some types of portable lifting

FIGURE 8-14 Portable lifting hoists, not common in MORE shops.

hoists have the controller on one of the pedestal legs, and others have a mobile controller that gives the operator complete lifting control away from the lifting zone. Both types of hoists have a remote pendant that allows the operator to safely inspect the lifting operation from any point around the vehicle.

Safety Locks Every vehicle hoist in the shop must have a built-in mechanical locking device so the vehicle hoist can be secured at the chosen height after the vehicle is raised. This locking device prevents the vehicle from being accidentally lowered and holds the vehicle in place, even if the lifting mechanism fails. You should never physically go under a raised vehicle for any reason unless the safety locking mechanism has been activated.

Ratings and Inspections All vehicle hoists are rated for a particular weight and type of vehicle. Never use them for any task other than that recommended by the manufacturer. Never use a vehicle hoist to lift a vehicle that is heavier than its rated limit. Most countries have regulations that require hoists to be periodically inspected, typically annually, and certified as fit for use. Before you use a vehicle hoist, check the identification plate for its rating, and make sure it has a current registration or certification label.

Engine Hoists **Engine hoists**, or mobile floor cranes, are capable of lifting very heavy objects, such as engines, while the engines are being removed from a machine or refitted. The engine hoist's lifting arm is moved by a hydraulic cylinder and is adjustable for length. However, extending the lifting arm reduces its lifting capacity because it moves the load farther away from the supporting frame. You can extend the supporting legs for stability, but the more you extend the arm and the legs, the lower the engine hoist's lifting capacity. The safe lifting capacity at various extensions is normally marked on the lifting arm. The engine or component to be lifted is attached to the lifting arm by a sling or a lifting chain. The sling and lifting chain must be rated as capable of lifting weights more than the engine or component being lifted and must be firmly attached before the engine hoist is raised. When the engine or other component has been lifted and slowly and carefully moved away from the machine, it should be lowered onto an engine stand or onto the floor (**FIGURE 8-15**).

FIGURE 8-15 A folded engine hoist. Engine hoists come in many sizes and lifting capacities.

FIGURE 8-16 Inspect to make sure all chains, fixtures, and riggings are in good condition.

FIGURE 8-17 Overhead cranes are common place in heavy equipment shops.

The farther off the ground an engine is lifted, the less stable the engine hoist becomes. When using these types of hoists or cranes, always make sure that the slings and rope, cables, and chains that are used are compliant with relevant regulations and do not exceed the load ratings (**FIGURE 8-16**).

Overhead Cranes Many heavy equipment shops are equipped with **overhead cranes** (**FIGURE 8-17**).

These must be used in accordance with local regulations and with the correct slings, ropes, and chains. The crane is only as good as the slings connecting it to the equipment to be moved. Operate the crane smoothly, slowly, and with caution. Don't rush. Always ask for assistance if required. In many cases, two people will be required to operate an overhead crane—one to operate the crane, the other as a lookout—to watch the load and guide it if necessary.

SAFETY TIP

Never use a hoist to lift any weight greater than the lifting capacity of the hoist, sling, chains, or bolts.

Using Lifting Equipment

Like many shop activities, using lifting equipment involves managing risks. Think carefully about what you are going to do, plan your activities, and check the equipment to make sure it is safe to use.

Using Engine Hoists and Stands Engine hoists are capable of lifting very heavy objects, which make them suitable for lifting engines. Make sure the lifting attachment at the end of the lifting arm is strong enough to lift the engine and is not damaged or cracked. When attaching the lifting chain or sling to an engine, make sure it is firmly attached and that the engine hoist is configured to lift that weight. Make sure the fasteners attaching the lifting chain, or sling, have a tensile strength that is more than the engine's weight. To keep from overstressing the sling, leave enough length in the sling so that when the engine is hanging, the angle at the top of the sling is close to 45 degrees and does not exceed 90 degrees. In areas where space is limited for lifting, you should use a spreader bar to aid the lifting operation (**FIGURE 8-18**).

FIGURE 8-18 Spreader bars provide mounting points to spread the loads weight, some are also adjustable.

The bar is a straight piece of reinforced steel that bridges across the lifting eyes and is connected by D-shackles. The bar's center has a ring or D-shackle that is attached to the crane for lifting. If removing an engine from an engine bay, lower the engine so that it is close to the ground after removal. If the engine is lifted high in the air, the engine hoist will be unstable. When moving a suspended engine, move the engine hoist slowly. Do not change direction quickly because the engine will swing and may cause the whole apparatus to tumble. To use engine hoists and stands, follow the guidelines in **SKILL DRILL 8-3**.

► TECHNICIAN TIP

- The engine hoist's load rating must be greater than the weight of the object to be lifted.
- Never leave an unsupported engine hanging on an engine hoist. Secure the engine on an engine stand or on the ground before starting to work on it.
- If using an engine stand, make sure it is designed to support the weight of the engine and that you have the correct number of bolts to hold the engine to the stand.
- Always extend the engine hoist's legs in relation to the lifting arm to ensure adequate stability.

Lifting heavy items is inherently dangerous. It is important for the MORE technician to know the basic principles of lifting items safely and properly. It is also important to know the different types of lifting devices in your shop, which ones require special certification or training, how to inspect them for proper operation and safety inspection certifications, and how to operate them properly and safely.

► TECHNICIAN TIP

When involved with a lift, never place yourself or a body part underneath the item being lifted or jacked during the lift. When overhead cranes are in use, stand well outside the danger area, and never stand

SKILL DRILL 8-3 Using Engine Hoists and Stands

1. Prepare to use the engine hoist. Lower the lifting arm, and position the lifting end and chain over the center of the engine.
2. Wear appropriate PPE, such as leather gloves, during the entire operation, beginning with inspecting the chain, steel cable, or sling, and bolts to make sure they are in good condition. Before you use the crane, make sure the chain or sling is rated higher than the weight of the item to be lifted. Also, ensure that the lifting arm is only extended to the length of its lifting capacity applicable to the weight of the item to be lifted. Only use approved lifting equipment—nothing homemade. Look carefully around the component that is about to be lifted, to determine whether it has lifting eyes or other anchor points.
3. If the engine or component has lifting eyes, attach the sling with D-shackles or chain hooks. If you need to screw in bolts and spacer washers to lift the engine, make sure you use the correct bolt and spacer size for the chain or cable. Screw the bolts until the sling is held tight against the component.
4. Attach the hoist's hook under the center of the sling, and raise the engine hoist just enough to lift the engine to take the slack up on the cable, chain, or sling. Double-check the sling and attachment points for safety. The engine's or component's center of gravity should be directly under the engine hoist's hook, and there should be no twists or kinks in the chain or sling.
5. Raise the engine hoist until the engine is clear of the ground and any obstacles. Slowly and gently move the engine hoist and lifted component to the new location with minimum ground clearance to prevent swinging and potential tilting of the whole crane.
6. Make sure the engine is positioned correctly. You may need to place blocks under the engine to stabilize it. Once you are sure the engine is stable, lower the engine hoist, and remove the sling and any securing fasteners. Finally, return the equipment to its storage area.

underneath an unsupported load. Only begin work underneath an item after it has been properly supported and all safety precautions inspected and followed. Always have an escape route planned when involved in a lift. Plan the fastest and most direct route to get out of danger should the equipment collapse, including a route that will be clear of any additional rolling or falling equipment should something go wrong.

Blocking Equipment, Devices, and Procedures

In this section, we examine the principles of supporting a heavy item by blocking, along with the associated blocking equipment and devices. Blocking can be defined as the procedures and devices used to support a load (**FIGURE 8-19**). Just as in lifting, when extremely heavy or large loads need to be supported, a specialist called a rigger can be used. Because riggers undergo a large amount of special training and education to safely and properly lift and support large and heavy items, they can be used for these critical jobs. The MORE technician can conduct a lifting or supporting operation for any job when a rigger is not required. When in doubt about the safe and proper planning, application, and use of lifting and supporting equipment and procedures—you must refer to the machines service information or a certified rigger.

For the case of the MORE technician, blocking is used to support a machine, component, or attachment before working on it—to prevent it from falling. Blocking is also used to support a concentrated load such as outriggers or to spread the load out when heavy items are resting on a surface. Because each job and application is different, only general safety and procedures can be suggested. Most equipment manufacturers' technical manuals will outline the specific procedures for blocking, and these should be followed. Here, we go over some basic principles.

Chocking

Chocks are blocks of material placed against a wheel to prevent undesired rolling movement. They should be constructed of a material that will not crush easily and of a size that the tire cannot roll over easily. Prior to lifting any wheeled piece of

FIGURE 8-20 Chocking on both sides of the tire before lifting prevents unintended movement of the equipment during the lift.

equipment, always chock in front and behind one of the tires to prevent unwanted rolling (**FIGURE 8-20**). Chocks should be placed on the downhill side of the vehicle. When possible, use two chocking points due to the weight shifting when the item is lifted. Also, ensure the item is locked out, to prevent anyone else from accidentally attempting to start or move the equipment.

Locking Lift Cylinders and Articulating Joints In-Place

Before jacking, lifting, or blocking a piece of equipment, ensure that hydraulic lift cylinders and articulating joints are mechanically locked in place to prevent movement. Never rely on the hydraulic pressure in a lift cylinder to prevent a part from falling (**FIGURE 8-21**). Furthermore, once a piece of equipment is raised to the desired height, *and before working underneath*, always ensure that buckets, forklift carriages, and other moveable equipment is blocked to prevent movement even in the event of a hydraulic system failure. When lifting equipment with articulating joints such as front-end loaders, or dump trucks in which the front and rear portion of the equipment has an articulating

FIGURE 8-19 Blocking can support an entire piece of equipment, a component, or an attachment while it is being serviced.

FIGURE 8-21 Always mechanically lock hydraulic lift cylinder in place before lifting a piece of equipment. Never trust your life to an O-ring!

FIGURE 8-22 When a machine's implement is rested on the ground, it should be extended so that it cannot move further.

joint, *always lock the articulating joint before lifting*. Failure to adhere to these rules has a very high likelihood of causing unintended equipment movement, possibly resulting in equipment damage, serious injury, or death.

If raising and locking the lift cylinder is not practical for the work being done, then the machine's implements should be rested on the ground so that they cannot move, as shown in **FIGURE 8-22**.

SAFETY TIP

Before working underneath any equipment, make sure it is properly supported. Inspect the blocking and/or supports, and check that wheels are chocked, articulating joints are locked, hydraulic lift cylinders are locked, and their ancillary equipment is supported. If something does not seem right, *stop* and check with a competent person or the equipment manufacturer's manual. Don't risk your life trusting someone else's improper work.

The following are some basic procedures to observe when blocking and supporting items. For further details, the machines service information or consult a certified rigger or rigging training resources.

- Use blocking when specified by the equipment manufacturer for a repair, and follow the manufacturer's instructions.
- Use blocking whenever working underneath a heavy item that has been lifted, to prevent it from falling if the lifting device were to fail.
- Use blocking whenever the weight of an item would cause damage to the item or the surface it rests upon. For example, do not lay an engine directly on the ground. Support it with blocking.
- Use blocking material that can withstand the concentrated load without deforming or splitting.
- The entire assembly of blocking equipment and materials is only as strong as the weakest part. *Ensure the materials and equipment selected can support a weight at least four times the weight of the item being supported.*

- Use blocking material that is square shaped and stable. Do not use round or triangular blocking.
- Park equipment on a flat, stable surface.
- Ensure chocks and parking brakes are used before lifting equipment.
- Inspect blocking equipment and materials for damage. Do not use blocking that is cracked or splintering.
- Use blocking materials that are at least twice as wide as they are tall, for stability.
- Use four points of contact when possible; if not, use at least two points of contact.
- When supporting equipment, ensure lift cylinders and articulating joints are mechanically locked to prevent shifting. *Never* rely on hydraulic pressure to keep an item from falling. (*Note: The equipment manufacturer usually provides mechanical locking devices for this purpose.*)
- Use blocking of the same material, type, and size so that the crush factor and capacity are uniform.

Just as with lifting, blocking and supporting equipment is both critical and a possible safety hazard. Ensure you follow the equipment manufacturer's recommendations when supporting an item. In addition, consult your shop's policy and procedure manuals and more experienced technicians when the need to block equipment arises. If you perform lifting and blocking duties often, ask your supervisor about specific training and technical resources to ensure you are complying with industry practices, the law, and safety regulations. Educating yourself on the proper techniques and equipment for blocking equipment will be time well spent.

► OSHA Standards for Proper Lifting Techniques and Equipment

K08005

As discussed previously, in the United States the government entity that sets rules for occupational health and safety is **OSHA (Occupational Safety and Health Administration)**. Because the operation of lifting devices can result in serious injuries and death, OSHA has many general and specific rules governing lifting and lifting devices. If you are working outside of the United States, consult your supervisor to determine what rules and standards must be followed for lifting and lifting equipment in your country. For the purposes of this chapter, we discuss OSHA and industry rules that apply in the United States.

First, let's set the proper attitude toward safety standards, OSHA, and other industry workplace safety and standards entities. Safety rules/regulations, OSHA, and other industry safety organizations are not your enemy or an impediment to getting the job done. They are your partner in ensuring the job gets done safely and correctly. Furthermore, you should take the rules, regulations, and advice of these entities seriously. Most of the safety rules and regulations exist because of a serious accident that caused damage to equipment or because someone was

seriously injured or died. It would be accurate to say that safety regulations were “written in blood.” Therefore, not following safety regulations puts yourself, your coworkers, and your equipment in danger.

Depending on what industry you are working in, as a MORE technician you may have to comply with additional industry regulations set by other government or industry entities. Consult with your supervisor to see what rules and regulations apply for lifting in your shop.

OSHA usually only sets general rules and regulations. It often defers the specifics of how to perform a task or operate a piece of equipment, or what technique or equipment to use, to the equipment manufacturer or another industry body more familiar with the exact situations a worker may encounter. Basically, following OSHA rules is not a substitute for following the equipment manufacturer’s recommendations or being proficient in your job. OSHA often refers to the general duty clause listed in Section 5(a)(1) of the OSHA act, which states:

Each employer shall furnish to each of his employees employment and a place of employment which are free from recognized hazards that are causing or are likely to cause death or serious physical harm to his employees.

Now, let’s review two areas for which OSHA has some rules and guidelines for lifting.

OSHA Guidelines for Manual Lifting

OSHA has some published training material and guidelines for manual lifting. OSHA does not have specific rules for, for example, the maximum weight a single person should lift. According to training material for manual lifting on the OSHA website (<https://www.osha.gov/SLTC/etools/electricalcontractors/supplemental/principles.html#lifting>). The following are some basic techniques for manual lifting.

- The person’s head is kept upright, looking straight ahead.
- When standing, the torso should not be bent more than 10–20 degrees from vertical. The natural curve of the spine is maintained.
- Pelvis and shoulders face straight ahead.
- Shoulders are relaxed and knees slightly bent.
- Do not leave items lying on the floor where they may cause a tripping hazard.
- Plan the route of travel and ensure it is clear *before* performing the lift.
- Lift within your *power zone*. The *power zone* is between mid-thigh and mid-chest height. This allows lifting with the least amount of effort.
- Use proper handholds on the items being lifted.
- Pulling is generally preferred to pushing and has a lower chance of injury.
- Rotation of tasks. Employees should rotate repetitive tasks that use different muscles to lower the chance of injury.

As concerns how much weight a single person should lift, OSHA published to its website a letter to clarify rules dealing with

this subject (https://www.osha.gov/pls/oshaweb/owadisp.show_document?p_table=INTERPRETATIONS&p_id=29936). OSHA defers to the National Institute for Occupational Safety and Health (NIOSH). NIOSH has a model that helps to determine the risk of injury based on the weight being lifted and several other factors (<http://www.cdc.gov/niosh/docs/94-110/>). These are only voluntary guidelines though. The lifting equation establishes a maximum load of 51 lb (23 kg). For a manual lift of weights above 51 lb (23 kg), OSHA recommends using other means such as these:

- A two-person lift
- A mechanical lifting device
- Breaking down items into smaller pieces

Although it may seem embarrassing or unneeded to ask another person for help or to use a mechanical lifting device, it is preferable to being injured and in pain, and possibly out of work.

OSHA Rules for Lifting Equipment

Several OSHA regulations deal with lifting equipment, depending on the type. We review some basic OSHA rules for several types of lifting equipment. Remember, it is your responsibility to research and know the applicable OSHA, industry standards, and equipment manufacturer specific rules and regulations.

- **Overhead and Gantry Cranes** (OSHA Standard 1910.179, 1926.1438)
 - The rated load of the crane shall be plainly marked and visible.
 - Equipment and all rigging devices must comply with the manufacturer’s recommendations.
 - Crane movement shall be clear of obstructions.
 - Functional inspection performed daily.
 - Full inspection performed should be monthly to every 12 months, depending on frequency of use.
 - Employee training is required.
- **Hoisting/Lifting Equipment with a Capacity of 2,000 lb or Less** (OSHA Standard 1926.1441)
 - The rated load should be marked on the lifting device.
 - Equipment and all rigging devices must comply with the manufacturer’s recommendations.
 - Post-assembly, (after being attached to the load), inspection is required to verify that equipment and connections meet the manufacturer’s specifications.
 - Employee training is required

You will notice that the common rules OSHA sets are that the personnel operating lifting equipment must be trained to use the equipment; the lifting capacity must be clearly marked; the equipment manufacturer’s recommendations must be followed; the equipment and load (once connected) must be inspected; and the maximum working load capacities of any devices and equipment must not be exceeded.

When guidance is needed about specific lifting procedures, rigging equipment and best practices, consult the machines service information or a certified rigger. For further details, refer to the OSHA standards for the specific equipment you are using, any applicable industry standards, and the lifting equipment manufacturer's information.

► Wire Rope Application and Use

K08002

Wire rope is simply rope made from wire. A wire rope consists of several strands of metal wire twisted into a helix shape along its entire length. Because of its usefulness, wire rope is used in many applications (**FIGURE 8-23**). Wire rope is often called cable.

Wire rope was initially developed as an alternative to metal chains. In a metal chain, a single failure in one chain link causes a catastrophic failure. In wire rope, a single failure of a wire does not lead to a catastrophic failure, as it has many other wire and wire strands to share the load should one fail. In addition, because of the twisted wire, internal friction between the wires also prevents a catastrophic failure should a single wire break. The most common material for wire rope is steel. Wire rope is used in many applications such as guy wires to support large towers, in suspension bridges, and for lifting and hoisting in cranes and elevators. Wire rope is quite strong, comes in many sizes, can come in very long applications, and is resistant to abrasion and crushing. Some important limitations to wire rope are listed here:

- It must be kept from bending, twisting, or kinking.
- Sharp bends and contact with sharp edges can cause damage.
- Wire rope conducts electricity.
- It must be inspected periodically (prior to use in critical applications such as lifting and rigging).

See **FIGURE 8-24** for an illustration of the different designs of wire rope.

FIGURE 8-23 Wire rope is used all around us in many devices and equipment, from a window regulator in a passenger car to the supporting cables in massive suspension bridges.

FIGURE 8-24 Wire rope comes in many designs.

Wire Rope End Terminations

A wire rope **end termination** is the treatment at the end or ends of a length of wire rope, usually made by forming an eye or attaching a fitting, and designed to be the permanent end termination on the wire rope that connects it to the load. Without the end terminations, the wire rope would not be able to connect to a load to perform a lift. The end terminations are just as important as the wire rope itself. An entire sling or rigging assembly is only as strong as the weakest part. Because of this, the end terminations and associated hardware can be a limiting factor on

the safe working load (SWL) of an entire sling or lifting assembly. Only use wire rope and slings with end terminations that have been proof tested by the equipment manufacturer and that are created by a certified rigger. Personnel that assemble end terminations to wire rope and slings must have specific knowledge and training to ensure they are done properly. Many shop accidents have been caused by lifting sling failures due to end terminations assembled improperly and/or not proof tested. If in doubt as to whether a wire rope end termination was done properly, consult a rigging manual from a reputable industry authority or a wire rope manufacturer. A good general rule of thumb is, if the wire rope and/or sling does not have the manufacturer's tag, it should be suspect.

Wire Rope Inspection

Because wire rope has a finite lifespan and is susceptible to wear and failure, regular inspections, and the frequency and type of inspection, are mandated by government and industry safety agencies, for continued proper and safe operation. Failure to follow government and industry regulations regarding inspection may result in civil or criminal penalties. Consult your country and industry regulations about inspection of wire rope and lifting equipment. See **SKILL DRILL 8-4** for general information that can be used as a rough guide for inspecting wire rope used for horizontal pulling/towing and vertical lifting.

As with any MORE equipment and procedures, safety is paramount when using wire rope and cables. Many people have been injured and even killed because of improper use,

application, and inspection of wire rope/cable. The proper use, application, and inspection of wire rope is not simple and requires special training and consulting technical data and manuals. Your proper knowledge will be the determining factor that ensures you can safely and properly use wire rope to perform your job. However, as stated previously, this chapter is not a supplement or replacement for proper technical training on the use, application, and inspection of wire rope and cabling.

SAFETY TIP

Only use wire rope, slings, and rigging hardware that has been proof tested by the equipment manufacturer, or a competent authority. *Do not use homemade lifting equipment and hardware.* Manufactured slings, hardware, and lifting devices are made using proven techniques and tested to ensure they can carry a specified load without failure or degradation. Homemade devices are not. Don't trust your lift to a homemade sling or end termination. A good rule of thumb: If it does not have the manufacturer's tag or stamping with the load rating on it—don't use it.

► Winch Design, Operation, and Troubleshooting

K08003, A08001

A **winch** is a mechanical device used to reel in (pull) or wind out (let out) horizontally a length of wire rope or chain. A winch used to vertically lift an object is considered a crane. Most

SKILL DRILL 8-4 Inspecting Wire Rope Applications Prior to Use (General External Physical Inspection)

1. Check wire rope for manufacturer's specification tag with name of manufacturer; date of manufacture, load capacity, and date of last inspection by a certified individual or authority. Do not use wire ropes or cables with an unknown load capacity.
2. If available, look up and utilize the specific inspection instructions from the cable manufacturer's website or technical data.
3. Visually inspect the end terminations and hardware for excessive corrosion and wear as well as for proper placement, tightness, breakage, or deformation. Repair or replace any end attachments showing signs of failure.
4. Ensure one end of the wire rope remains stationary. While wearing thick gloves, wrap a thick towel around the wire rope. Gripping around the towel and wire rope tightly, run the towel down the entire length of the wire rope to the end attachments. You will be able to feel any wires that have separated on the outside of the wire rope. Now, repeat the same thing, running the towel the other direction on the wire rope to the end. Note and mark any broken wires found. Although replacement guidelines for wire rope vary slightly with the design of the rope, a common replacement criteria would be if there are six or more broken strands in any one rope lay, any broken wires in the valley of the lays, (the inside), or any broken strands at an end termination.
5. While performing the above step, visually inspect the outside of the wire rope, paying attention to the following failure conditions:
 - Kinks
 - Birdcages
 - Core protrusions
 - Broken or frayed wires
 - Changes in wire rope diameter, indicating an internal core failure
 - Excessive wear and abrasion

The above failures and or rope conditions are not repairable and depending on severity will require rope replacement.
6. Ensure the entire length of the wire rope/cable is inspected. If any failures or damage are found, consult the wire rope manufacturer's inspection criteria to determine whether replacement is needed.
7. *Important notes:* Some critical applications may require further inspection of the wire rope/cable, such as magnetic or other nondestructive inspection techniques. Consult the wire rope manufacturer's manual as well as applicable government and industry standards for more information.

FIGURE 8-25 A piece of mobile off-road equipment (MORE) with a winch.

winches utilize wire rope. We focus here on winches that utilize wire rope to move an item horizontally (**FIGURE 8-25**).

When conducting a winching operation, safety is paramount. Consult the winch manufacturer's technical manual for specific instruction on the proper use, inspection, and applications for the winch you are using. In addition, follow these basic rules when using a winch.

- Know the winch and the wire rope's rated capacity, and do not exceed it.
- Keep all nonessential personnel well away from any active winching operations.
- Designate a person in charge (PIC) for any winching operation. That person will be responsible for the overall safety and effective operation of the winching procedure.
- *Never* allow anyone to step over or under the winch's wire rope/cable during a winching operation.
- If needed, place a winch blanket on the cable to minimize snapback in the event of wire rope/cable failure.
- Ensure everyone has an escape route planned should the wire rope break during an operation.
- Ensure the wire rope was properly inspected prior to use.
- Use the shortest length of wire rope needed to perform the task. Longer lengths of wire rope have a greater danger area if they should break.

Improper spooling is a critical issue that can cause unneeded damage to the wire rope and result in unneeded hours to correct. Follow the winch manufacturer's instructions for how to spool/reel in the winch cable properly. Ensure that the wire rope has tension when it is reeled back into the spool. In addition, if the spool reel has grooves, follow the grooves when winding the spool. Ensure that when winding multiple layers of wire back into the reel, the layers do not get out of sync with the previous layer. The winding of the first layer is critical, as all the other layers will naturally follow. Ensure the first wind of the first layer is in the groove, pressed to the furthest outside

of the spool flange. Then have each successive wind press close to the previous one without stacking on top of it. When the first layer is established properly, simply follow the bottom layer, and do not leave any gaps. If the wire rope gets out of sync, gently unwind the spool until the bad portion has been released. Then rewind the spool until all the cable has been placed properly on the spool.

► Towing, Transporting, and Coasting Precautions

K08004

As with most wheeled vehicles and equipment, MORE can unexpectedly break down and not be able to move under its own power. In addition, most MORE equipment cannot legally travel on the roadway, and so must be towed on a trailer to the site of operations. In this section, we discuss some basic precautions to towing, transporting, and coasting operations for MORE.

Due to the weight and complexity of the drive and steering systems of much MORE, there should be specific towing and transporting instructions from the equipment manufacturer. Whenever a piece of MORE must be towed or transported, you must consult the equipment manual for the equipment being towed, as well as the manual for the equipment selected to perform the towing or transporting. The primary goal of any towing or transporting operation is move the equipment without damage to either the towed or towing equipment, or injury to personnel involved.

SAFETY TIP

Before towing or transporting any MORE, consult the equipment manual for specific instructions and safety precautions. The equipment manufacturer has more knowledge than you regarding the proper towing and transportation of its equipment.

General Precautions for Towing Operations

For towing operations, following these basic guidelines in addition to the equipment manufacturer's manual.

- Always consult the equipment manufacturer's manual for specific instructions, required equipment, and safety precautions for the towed, towing, and any additional equipment before starting a towing operation.
- Ensure that the load ratings of all the towing attachments on the equipment to be towed, the equipment doing the towing, and any attaching devices is known.
- Ensure that load and capacity ratings are not exceeded.
- Ensure all nonessential personnel are kept clear of the operation.

- Ensure all essential personnel use the proper PPE.
- Ensure the brakes on the tow vehicle and trailer, towed vehicle, and other equipment are working before starting the operation.
- Maintain a reasonable and controllable speed.

General Precautions for Transporting Operations

When transporting MORE on a flatbed style or lowboy trailer, also known as a float, some additional precautions must be made. In this case, you must ensure that the MORE is securely fastened to the trailer using appropriate tie down. You must ensure that the equipment is restrained in place from any movement forward, backward (aft), vertically, and horizontally (side-ways). Failure to adequately restrain the equipment to the trailer may cause the equipment to break loose during acceleration, deceleration, cornering, or going over a rise or bump. This can cause the equipment to fall off or impact the cab of the towing vehicle, resulting in serious equipment damage, personal injury, and even death.

You are probably already aware that the operator of a vehicle or piece of equipment is responsible to ensure that the load being carried is adequately restrained and secure.

Many countries' transportation industry standards set specific criteria for cargo restraint that must be applied to prevent movement. The **restraint criteria** are used to determine the proper amount of restraint that must be applied to a piece of cargo to prevent movement in the forward, rearward/aft, lateral, and vertical directions. The restraint criteria are given as a number followed by the letter "g" (example: 0.8 g). What this means is that the criteria references the normal acceleration due to gravity (g) on earth, which is 32.2 ft/s^2 (9.8 m/s^2). So, 0.8g would be 32.2 ft/s^2 , multiplied by 0.8; which is 25.76 ft/s^2 . This becomes the acceleration of mass due to gravity that must be restrained. The weight of an object (W) is its mass (M) multiplied by the acceleration due to gravity (g); $W = M \times g$. So, an item that weighs 75,000 lb and must be restrained in the forward direction to 0.8 g must only be restrained to $75,000 \text{ lb} \times 0.8 = 60,000 \text{ lb}$ in the forward direction. If the restraint criteria were 1.0 g, then it would be 75,000 lb. If the restraint criteria were greater than 1.0 g, then it would be greater than 75,000 lb. This is used to determine that actual amount of restraint that must be provided by the restraint devices used. For transporting operations, follow these basic guidelines in addition to the information provided in the equipment manufacturer's manual.

- Always consult the equipment manufacturer's manual for specific instructions, required equipment, and safety precautions.

FIGURE 8-26 Proper restraints are essential when transporting equipment.

- Ensure that the capacity ratings of all the tie-down and restraint attachments, and tie-down devices are known.
- When determining actual restraint provided by the tie-down devices, the lowest rating of the attachment points or tie-down equipment will be used (a tie-down chain rated at 10,000 lb attached to a tie-down ring rated at 5,000 lb has a capacity of 5,000 lb).
- Always apply tie-down devices in symmetrical pairs (**FIGURE 8-26**).
- Do not mix and match tie-down device types in the same restraint direction (a nylon strap will stretch a different amount under load than a metal chain).
- Ensure the brakes on the tow vehicle and trailer, towed vehicle, and other equipment are working before starting the operation.
- Maintain a reasonable and controllable speed.
- Remember that with equipment on your trailer, your center of gravity will be higher, and the vehicle and trailer more prone to tipping over.

Coasting can be very dangerous, as it is often uncontrolled. Avoid coasting operations unless there is no other way to recover a piece of equipment. Because most MORE is very heavy, there are not many things that can stop or control a piece of MORE that is coasting uncontrolled. Perform a thorough operational risk management (ORM) analysis, and implement proper controls before performing any coasting operation. Try using another, larger, piece of MORE equipped with a winch to attach to the disabled equipment to slow and control its decent rather than free fall coasting.

► Wrap-Up

As you service MORE, you will be tasked to lift, tow, and move heavy equipment and parts. This carries inherent safety risks that can damage equipment, property, and result in injury to yourself and others. Ensure that you know the proper regulations, rules, equipment, and procedures to use. If you don't know, find out from a competent person or an authoritative source. Don't place yourself and others at risk by not knowing the correct way to perform a lifting, blocking, or towing operation. Conversely, don't place your life in someone else's hands without verifying everything has been done correctly.

Ready for Review

- ▶ Always use the proper lifting techniques when moving heavy objects.
- ▶ The safe working load indicates the operating capacity for lifting equipment.
- ▶ Lifting equipment includes vehicle hoists, floor jacks, jack stands, engine and component hoists, chains, slings, and shackles.
- ▶ Periodically check and test lifting equipment; consult the test certificate if available.
- ▶ Jacks can be classified by the type of lifting mechanism they use: hydraulic, pneumatic, or mechanical.
- ▶ Jack types include floor jacks, high-lift (farm) jacks, bottle jacks, air jacks, scissor jacks, sliding bridge jacks, and transmission jacks.
- ▶ Choose jacks according to size and lifting capacity.
- ▶ Jack stands support a vehicle's weight when it has been raised; always use jack stands in pairs.
- ▶ Vehicle hoists raise the vehicle to allow technicians underside access.
- ▶ Never use a vehicle hoist without activating the safety lock, or for lifting a vehicle heavier than the rated limit.
- ▶ Make sure a machine has enough clearance over the lifting mechanism.
- ▶ Engine hoists can lift heavy objects out of a machine and onto an engine stand.
- ▶ Check for damage before using an engine hoist, and make sure all components have the lifting capacity needed for the task.
- ▶ Always have a safe attitude when using tools and equipment, and wear necessary personal protection equipment.
- ▶ Always inspect lifting, rigging, and blocking equipment and devices prior to use.
- ▶ Never stand underneath an item being lifted.
- ▶ Always have an escape route planned should something go wrong during a lifting, towing, or coasting operation.
- ▶ Never sacrifice your body to save a piece of equipment from damage or falling.
- ▶ Don't exceed the rated capacity of a lifting, blocking, or towing device.

Key Terms

blocking Includes blocking, cribbing, jack stands, timbers, dunnage, and any other devices or equipment designed to support a load in a stationary position.

blocking devices Also referred to as blocking and cribbing. These include blocking, cribbing, jack stands, timbers, dunnage, and any other devices or equipment designed to support a load in a stationary position.

cable clip A device consisting of a U-bolt, a saddle, and two nuts, used to bind a loop at the end of a wire rope.

center of gravity (CG) Also called the center of balance. The center of gravity, or CG, of an object is the point, or position, at which the item's weight is evenly dispersed, and all sides are in balance. If the item were to be supported in a direct vertical axis from the center of gravity, it would balance perfectly.

chain blocks A chain block is a piece of equipment used to lift heavy items. The typical block, also known as chain falls, consists of two grooved wheels with a chain wound around them in the same fashion as a block and tackle. The chain wound around the two wheels creates a simple machine that uses the leverage and the increased lifting ability created by the two wheels to lift heavy weights.

chocks Blocks of material placed against a wheel to prevent undesired rolling movement.

cribbing Also referred to as blocking. This includes blocking, cribbing, jack stands, timbers, dunnage, and any other devices or equipment designed to support a load in a stationary position.

end termination The way the end of a wire rope is treated, usually by forming an eye that becomes the attachment for the wire rope.

engine hoist A small crane used to lift engines.

gantry crane A crane similar to an overhead crane except that the bridge for carrying the trolley or trolleys is rigidly supported on two or more legs running on fixed rails or other runway.

hoisting The action of lifting a load using cables or ropes.

hydraulic hoist A type of hoist that the vehicle is driven onto that uses two long, narrow platforms to lift the vehicle.

hydraulic jack A type of vehicle jack that uses oil under pressure to lift vehicles.

jack stands Metal stands with adjustable height to hold a vehicle once it has been jacked up.

lifting equipment Also known as lifting gear, any equipment or devices used to lift a load vertically. This can include jacks, a block and tackle, vacuum lift, hydraulic lift, hoist, gantries, windlasses, cranes, forklifts, slings or lifting harnesses, rigging, wire rope/cables, and any other items used to lift a load vertically.

mechanical jack A type of jack that utilizes mechanical power to provide lifting. A screw jack is a type of mechanical jack.

Occupational Safety and Health Administration (OSHA) The agency that assures safe and healthy working conditions by setting and enforcing standards and by providing training, outreach, education, and assistance.

overhead crane A crane with a movable bridge carrying a movable or fixed hoisting mechanism and traveling on an overhead fixed runway structure.

pneumatic jacks A type of vehicle jack that uses compressed gas or air to lift a vehicle.

portable lifting hoists A type of vehicle hoist that is portable and can be moved from one location to another.

Reference Datum Line (RDL) The arbitrary reference point from where the center of gravity is measured. Determined by the equipment manufacturer.

restraint criteria Used to determine the proper amount of restraint that must be applied to a piece of cargo to prevent movement in the forward, rearward/aft, lateral, and vertical directions.

rigger A person who specializes in lifting and moving heavy objects.

rigging/rigging gear All the components used to attach the mechanical hoisting equipment to the load being lifted. This can include rope, wire rope/cables, slings, shackles, eyebolts, eye nuts, links, rings, turnbuckles, rigging hooks, compressions hardware, rigging blocks, load-indicating devices, and precision load positioners.

safe working load (SWL) The maximum safe lifting load for lifting equipment.

test certificate A certificate issued when lifting equipment has been checked and deemed safe.

towing equipment and devices Equipment or devices used to pull, or tow, a load horizontally.

vehicle hoist A type of vehicle lifting tool designed any to lift the entire vehicle.

winch A mechanical device used to reel in (pull) or wind out (let out) horizontally a length of wire rope or chain.

wire rope clips Fitting for clamping parts of wire rope to each other.

Review Questions

- Whenever possible, _____ points of contact should be used when blocking a piece of equipment.
 - two
 - one
 - three
 - four
- When lifting an object using a hoist from above, the lifting devices should be attached _____ the item's center of gravity.
 - above
 - below

- on either side of
 - with no reference to
- When an item is lifted from above using a two-chain hoist, with the chains at a 30-degree angle from the horizontal, the actual lifting capacity of the chains will be _____ than if they were placed vertically.
 - less
 - more
 - the same
 - The actual lifting capacity of an overhead crane is limited by _____.
 - the crane's capacity/rating
 - the rigging device(s) capacity/rating
 - the attachment points on the item being lifted
 - the lowest capacity/rating between the crane, rigging, and attachment points
 - When lifting an object using a jack from below, the jacking points are best if they are _____ the item's center of gravity.
 - above
 - below the level of
 - on either side of
 - below and in line with
 - True/False. It is acceptable to mix types and materials of lifting and rigging equipment attached to the same load, if their capacity is not exceeded.
 - True
 - False
 - True/False. A lifting device with a capacity less than 2,000 lb does not require operator training.
 - True
 - False
 - When securing a piece of equipment for transportation onto a flatbed or lowboy trailer, _____ restraint will prevent the item from tipping over and falling off the side of the trailer.
 - forward
 - aft/rearward
 - vertical
 - lateral
 - True/False. When a piece of equipment is properly restrained and secured for transportation onto a flatbed or lowboy trailer; the trailer with the equipment on it will be restrained from tipping over when going around corners.
 - True
 - False
 - Operators of lifting equipment are required to be knowledgeable of and adhere to which of the following standards and guidelines?
 - OSHA
 - The equipment manufacturer's
 - Industry standards
 - All of the above

ASE Technician A/Technician B Style Questions

1. Technician A says that wire rope must be inspected before use, and weekly. Technician B says that wire rope must be inspected before use and as often as the wire rope manufacturer, or government or industry standard requires. Who is correct?
 - a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B
2. Technician A says the parking brake must be applied before jacking a piece of wheeled equipment. Technician B says chocks must be installed in front of and behind a wheel before jacking a piece of equipment. Who is correct?
 - a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B
3. Technician A says that a wire rope can have broken wires along its length and still be useable. Technician B says that if there are broken wires at an end termination, the rope should be replaced. Who is correct?
 - a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B
4. Technician A says that you must still ensure that implements are supported, even with lift cylinder locks installed. Technician B says that because lift cylinder locks are installed, the implement is considered locked in place, and it is not necessary to support the implement. Who is correct?
 - a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B
5. Technician A says that articulating joints must be mechanically locked before lifting a piece of equipment. Technician B says that hydraulic lift cylinders must be mechanically locked and placed in the full down position prior to lifting a piece of equipment. Who is correct?
 - a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B
6. Technician A says that government standards such as OSHA are the most correct source of information on how to properly utilize a specific piece of lifting equipment. Technician B says that industry standards such as rigging manuals are the most correct source of information on how to utilize a specific piece of lifting equipment. Who is correct?
 - a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B

7. Technician A says that a noticeable change in the diameter of a length of wire rope may indicate internal failure and require replacement. Technician B says a length of wire rope that has a birdcage in it can be repaired by straightening and then wrapping the area in steel wire. Who is correct?
- a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B
8. Technician A states that blocking is placed under an object to provide support. Technician B states that blocking is placed under an item to distribute the weight over a larger area. Who is correct?
- a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B
9. Tech A says that you should not use a piece of lifting or jacking equipment with an expired test certificate. Tech B says that you should perform an inspection of all lifting and jacking equipment prior to use. Who is correct?
- a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B
10. Tech A says that when towing a piece of heavy equipment, use the highest rated towing device you have available. Tech B says that you should consult the equipment manufacturer's manual and follow the specific procedures for towing. Who is correct?
- a. Tech A
 - b. Tech B
 - c. Both A and B
 - d. Neither A nor B

CHAPTER 9

Principles of Electricity and Electrical Circuits

Knowledge Objectives

After reading this chapter, you will be able to:

- **K09001** Identify and explain the functions of the electrical elements of the atom.
- **K09002** Identify and describe conductors, insulators, and semiconductors.
- **K09003** Define and explain concepts of voltage, amperage, and resistance.
- **K09004** Describe the differences between the electron theory of current movement and the conventional current theory.
- **K09005** Describe the differences between alternating and direct current.
- **K09006** Describe the differences between electrical and electronic circuits.
- **K09007** Describe the heating effect of current in an electrical circuit.

Skills Objectives

After reading this chapter, you will be able to:

- **S09001** Differentiate between electrical units of measurement for voltage, amperage, resistance, and power.
- **S09002** Calculate energy consumption in a heating circuit.

► Introduction

Not long ago, a typical mobile off-road machine had fewer than 20 electrical circuits. Lighting, starting, and charging were the most significant electrical systems along with a few other electrical accessories like the horn and wipers. Today, the number of electrical circuits has increased into the hundreds, and very few mobile off-road machine systems operate without electronic control (**FIGURE 9-1**). Where the radio was once the most sophisticated electrical device, microprocessors containing millions of transistors control the traditional electrical systems, such as lighting and accessories, and the software contained in the control modules operates hydraulics, transmissions, engine, and onboard interactive display systems. Increasing sophistication of mobile off-road electrical systems include electronic machine and implement controls, hybrid electric powertrain, and telematics, which is monitoring and control of equipment using satellite, cell phone, and Internet-based equipment communication.

Today's electrical system components are no longer separated into distinct systems. Electronic control modules (ECMs) provide electrical signals to operate individual electrical components. The modules are then connected by onboard networks, enabling the control of the electrical system to be distributed over many electronic control modules (**FIGURE 9-2**). Networking electrical system components adds new equipment features

FIGURE 9-1 Electronic controls extend to every machine system.

that can enhance safety, performance, and operator comfort simply by adding only software and a twisted pair of wires to connect all the equipment ECMs. For example, receiving a hands-free cell phone call today could automatically mute the radio volume; leaving the operator's seat will simultaneously engage the parking brake and disable the hydraulic implements; a grade control system using laser, sonic, and GPS technology provides in-cab guidance to operators. Electronic throttle control matches horsepower and torque to meet the demands of the application. Electrohydraulics provide superior implement control that reduces heat buildup and saves fuel.

What is the point being made? The technology in today's mobile off-road electrical systems is both complex and sophisticated. More than ever, a successful and valued technician needs to have a sound understanding of electrical principles underlying mobile off-road electrical systems technology. Arguably, the technician's most essential skills are to understand principles of electricity, analyzing electrical problems and comprehending electrical system and component operation, plus knowing how to use test equipment to diagnose electrical problems.

► Electrical Fundamentals

K09001

Understanding the behavior of electricity can be more difficult than understanding mechanical concepts such as four-stroke cycle engine operation or braking fundamentals, because electricity itself cannot be seen, but its effects can be felt. At the same time, electricity is governed by the laws of science, so learning how electricity behaves can be approached in a logical manner, as with any other subject. By applying yourself, over time it will make more and more sense. This chapter explores basic principles about the nature of electricity and how it behaves. To get started, it is useful to know there are good analogies for how electricity behaves, which are helpful to understand different aspects of electricity's properties. Visualizing electrical concepts using these comparisons helps many learners to more easily understand electrical principles. In fact, one analogy is to think of electricity as nothing more than the movement of particles from one point to another. For example, imagine a line of marbles rolling through a tube or the flow of water through a pipe. The moving marbles or flow of water has energy that can be harnessed and made to

You Are the Mobile Heavy Equipment Technician

When measuring the amount of amperage drawn by a starting motor cranking, a 13.6L Deere Power Tech engine, a technician observed close to 900 amps of current were needed. The engine cranking speed was normal and close to 200 rpm, but the technician observed light smoke rising from some of the battery cable connections. After replacing all three batteries and making sure all batteries were fully charged, only 400 amps of current were needed to start the engine. The engine then cranked at close to the same speed as before the batteries were replaced.

1. Explain why the starting motor used more amperage before replacing the machine's batteries than after replacing the batteries.
2. If it were possible for the 12-volt starting motor to be used in a 24-volt circuit, what would you predict would happen to the amount of amperage drawn by the starting motor?
3. Explain why smoke was rising from the battery cable connections when the cranking amperage was high. Include the name of the applicable electrical law in your explanation.

FIGURE 9-2 Contemporary mobile off-road machine system architecture. All electronic control modules are connected to an onboard machine network, which provides distributed control of the electrical system.

perform work or some specialized function. Electrical devices can extract the energy from moving particles (**FIGURE 9-3**). The energy can be converted into a variety of other forms such as light, heat, sound, electrical signals, or magnetic fields, which are then used to operate motors, solenoids, or relays. That is where some of electricity's magic comes in. Moving these electrical particles involves using positive and negative charges that are governed

FIGURE 9-3 Electrical devices, such as this ECM, extract energy from moving particles.

by basic **electrostatic theory**—unlike charges are attracted to one another (positive to negative), and like charges are repelled by one another (positive repels positive, negative repels negative) (**FIGURE 9-4**). These forces of charge repulsion and attraction are called electrostatic force and are foundational to produce the flow of electrical current and operate all electrical devices. Electrostatic forces of repulsion and attraction are incredibly powerful, and the energy they contain can be harnessed by electrical devices to perform work.

Electrostatic Law Summary

- A proton's (+) charge repels another proton's (+) charge.
- An electron's (–) charge repels another electron's (–) charge.
- A proton's (+) charge attracts an electron's (–) charge.

As you continue, remember that electricity is the movement of charged particles from one place to another, pushed or pulled by electrostatic force.

Basic Electricity

All questions about the nature of electricity lead to the composition of matter. All matter is made up of atoms, as shown in **FIGURE 9-5**. Atoms are composed of electrons, protons, and neutrons. Positive electrical charges are found on protons, negative charges on electrons, and neutrons have no electrical charge. Neutrons and positively charged protons make up the nucleus of an atom. Neutrons are the electrical glue that

FIGURE 9-4 Summary of electrostatic laws.

FIGURE 9-5 A model of the atom based on a 1910 understanding. The model is useful to understand electrical principles.

prevents the electrostatic forces of repulsion between the protons from bursting the nucleus. Moving around the outside of the nucleus are one or more negatively charged electrons. Electrons travel in different layers or shells around the nucleus. Each shell can contain only a specific maximum number of electrons.

With equal numbers of protons and electrons, the charges within an atom balance each other, leaving the atom with no overall charge. It is the goal of every atom to achieve this state of balance between the electrical charges. Only electrons can be removed or added to an atom, and not protons. If an atom loses or gains an electron, it is called an ion. The term “ion” simply means the atom has an imbalance of electrical charges due to the gain or loss of electrons. An atom with more electrons than protons has an overall negative charge and is called a negative ion. Ions are unstable, and the atom wants to return to a state where the electrical charges are balanced or neutral. In the case of a negatively charged ion, the presence of an extra electron causes the forces of repulsion to try to push the electron away from the atom, as illustrated in **FIGURE 9-6**. A deficiency of electrons gives the atom an overall positive charge and is called a positive ion. It is also not electrically balanced and will try to achieve a state of balance between the positive and negative charges and become neutral. In this case, the positively charged protons will pull on any available electron to return the atom to a state of balance between electrical charges.

FIGURE 9-6 Imbalances between the number of electrons and protons produces an electrical charge.

If a negative ion and positive ion are close enough, the negative charge on the negative ion exerts a repelling force on the extra electron, causing it to be pushed away from its atom; at the same time, the positive ion exerts an attracting force on the extra electron. These forces of repulsion and attraction cause the electron to be pushed from one atom and pulled toward the positive atom, balancing the charges on both atoms. It is this movement of electrons from one atom to another that is called electricity.

► Conductivity

K09002

Not all atoms can give up or accept electrons easily. Materials that hold electrons loosely enable electrons in their outer shell to move easily. These materials are categorized as **conductors**, whereas materials that hold electrons tightly and prevent electron movement are called **insulators**. The electrons that are only loosely held by the positive charges in the nucleus can move when another force strong enough can overcome the forces of attraction holding an electron in the atom. In fact, atoms with the fewest electrons in their outer shell are the best conductors. Copper (Cu) is an example of a metal with only one electron in the atom's outer shell (**FIGURE 9-7A**). Because a single electron is held loosely by the nucleus, copper makes an excellent conductor. By contrast, argon (Ar) is a noble gas, meaning that it generally does not form molecules and so is an insulator (**FIGURE 9-7B**). Semiconductors such as silicon (Si) (**FIGURE 9-7C**) are discussed in greater detail in the section Semiconductors. **TABLE 9-1** shows how the conductivity of other metals compares to the conductivity of copper. Metals typically have lots of easily moved electrons, which make them good conductors. But it's not just metals that conduct electricity; liquids can too. Electrolytes are liquids that conduct electric current. The liquid inside a lead-acid battery is an example of where electrolyte is used. Under some circumstances, air and other gases can conduct electricity, which is seen when a spark crosses an air gap. The term "plasma" is used to describe ionized gases that conduct electrons.

► Understanding Current

K09003, S09001

Understanding conductivity is the foundation for understanding the flow of electrical current. This section discusses the basics of current movement, how quickly electrical currents move, and in what direction.

Movement of Electric Current

The forces that can move electrons on or off an atom include the following:

- Light
- Heat
- Pressure
- Friction
- Magnetic fields
- Chemical energy

A

B

C

FIGURE 9-7 A. Conductor. B. Insulator. C. Semiconductor.

The force applied by each of these energy sources against an electron determines how fast an electron is moved from one atom to the next. This is like hitting a baseball (**FIGURE 9-8**). The harder the ball is hit, the faster it travels. As an electrical concept, the speed of electron travel from atom to atom is voltage. A **volt**

TABLE 9-1 Conductivity of Different Metals Compared to Copper

Conductor	Conductivity Compared to Copper
Silver	1.064
Copper	1.000
Gold	0.707
Aluminum	0.659
Zinc	0.288
Brass	0.243
Iron	0.178

is the unit used to measure the electrical potential difference between two points or electrical pressure (**FIGURE 9-9**). Higher electron **voltage** means the electrostatic forces pushing or pulling an electron are stronger. To understand better the concept of voltage and other characteristics of electrical current, the

hydraulic model of electricity is a useful visualization. Essentially, the hydraulic model compares the flow of electricity to water movement through pipes and plumbing components. When using an analogy of electricity represented as water in a pipe, the concept of voltage is like pressure (**FIGURE 9-10**).

FIGURE 9-8 The force moving electrons through a circuit is voltage. The greater the force pushing the electrons, the higher the voltage.

FIGURE 9-9 Electricity is the movement of electrons from atom to atom. The force moving electrons through a circuit is voltage.

FIGURE 9-10 The concepts of electrical current flow: voltage, amperage, resistance.

Just as higher pressure in a pipe moves water faster, high voltage means electrons move with greater speed from atom to atom.

Amperage is another electrical term used to describe the movement of electrons or electrical current. The unit of measurement for amperage is the **ampere**. Although voltage can describe the average force of one or many electrons, amperage measures how many electrons are in movement at one time. When using the analogy of water in a pipe to describe the movement of electrons, amperage is like the number of gallons or liters moving past a point in the pipe per second of time. In a sense, amperage really describes the volume of electron flow. When describing the flow of electricity, a circuit's voltage and amperage together, the term "electric current" is used. Without both of these two electrical properties operating, there can be no electric current. No voltage means no pressure is available to push or pull electrons. No amperage means there are no electrons to move in a circuit. Please note, often the term "current" is used in some textbooks to describe amperage. Throughout this textbook, "current" describes the flow of electricity, which needs both voltage and amperage.

Together, the force of the electricity (volts) and volume of electrons moving in a circuit (amperage) function to perform work. To predict the amount of power available to perform work, a simple calculation answers the question about how much work can be done per second of time. Watts or wattage

is the unit for measuring power. Wattage is a function of Voltage $\times$ Amperage, or Power = Volts $\times$ Amps. For example, if one wanted to find out how many amps are required to crank an engine over with a 10-horsepower starting motor, the calculation would be this: Because 746 watts is defined as being equal to 1 hp, $10 \text{ hp} \times 746 \text{ watts} = 7,460 \text{ watts}$. If the available voltage is 12 volts, the equation would be:

$$7,460 = 12 \times \text{amps and } 7,460/12 = 621.6 \text{ amps}$$

Now this calculation does not take into consideration energy losses due to friction, circuit resistance, the efficiency of the starting motor, and so on. If 24 volts were available rather than 12 volts, the same power could be produced with half the amperage, or 311 amps. If only 6 volts were powering the starting motor, 1,243 amps would be needed.

Another important electrical concept is resistance. **Electrical resistance** is a material's property that reduces voltage and amperage in an electrical current. Electrical resistance is similar to the concept of friction. Like friction, which can slow objects down, anything that slows down the speed of electron movement is considered a **resistor**. Factors that determine the amount of resistance in a circuit include those listed in **FIGURE 9-11**.

1. *Type of material:* Conductors vary in the strength with which they hold electrons.
2. *Length of the conductor:* As length of a circuit or conductor increases, electrons travel farther and lose some energy.

FIGURE 9-11 Factors affecting resistance in a circuit.

FIGURE 9-12 The forces of repulsion cause electrons to move to the outer surface of a conductor. Current flows in the outer 10–30%. Larger diameter wire and stranded wire with more surface area conduct current with less resistance.

3. **Diameter of the conductor:** The larger the conductor, the greater the capacity to carry current (**FIGURE 9-12**).
4. **Temperature of the conductor:** Electrons require more energy to move through a conductor as its temperature increases.

Resistors convert the energy in current flow to other forms of energy. Often resistance produces only heat. But electrical devices can also harness and convert electrical energy into other forms such as light, sound, movement, magnetism, and electrical signals carrying information. Electrical devices using electrical energy are called **loads** and always have some resistance (**FIGURE 9-13**).

The electrical unit for measuring the amount of resistance in a DC circuit is an **ohm**. The term is named after the person who discovered that 1 volt of electrical pressure is required to

push 1 amp of current through a circuit if the circuit has a resistance of 1 ohm (**FIGURE 9-14**).

This relationship is known as **Ohm's law**. Stated mathematically, Ohm's law is:

$$\text{Voltage} = \text{Resistance} \times \text{Amperage}$$

Restating Ohm's law using a hydraulic analogy, 1 psi of water pressure is needed to push 1 gallon of water, in 1 second, through a pipe having a diameter of 1 inch.

Although the hydraulic analogy is not perfect, it provides a good visual image for remembering that, according to Ohm's law, increasing voltage in a circuit is like increasing water pressure. Just as more water flows through a pipe when water pressure is higher, more amperage flows through a circuit with higher voltage if the resistance or restrictions remain the same. Likewise, making a smaller restriction in a pipe is like increasing a circuit's resistance. Just as water pressure and volume drop in a narrower or restricted pipe, voltage and amperage are reduced with increased circuit resistance. The Greek letter omega (Ω) represents ohms, which is the unit used to measure resistance. Observing the relationship between the three factors of Ohm's law leads to the following conclusions:

If voltage is held constant in a circuit:

Amperage increases if resistance decreases.

Amperage decreases if resistance increases.

If resistance is held constant in a circuit:

Amperage will increase if voltage increases.

Amperage will decrease if voltage decreases.

If amperage is to remain the same in a circuit:

Voltage must increase if resistance increases.

Voltage decreases if resistance decreases.

FIGURE 9-13 The analogy to resistance in the hydraulic model of current flow is a restriction in a pipe.

FIGURE 9-14 An ohm is the measuring unit for resistance. 1 volt of pressure is required to push 1 amp through 1 ohm of resistance.

Resistance produces a decrease or drop in voltage. That is a very important electrical concept to apply when troubleshooting problems in electrical circuits. An ohmmeter can be used to measure resistance, but learning how to measure voltage drop in a circuit with a voltmeter is one of the most helpful ways to identify unwanted resistance in an electric circuit. In off-road

equipment, electrical system voltages are 12- or 24-volt systems; this means voltage is usually constant (except for battery or alternator failure), so resistance will be the main cause of low voltage issue within a circuit. Understanding how to measure voltage drops is covered in the chapter Electrical Test Instruments.

► Direction of Current Flow

K09004

Only electrons can be moved on and off an atom to create either a negative or positive electric charge. A charge is created when a source of energy, such as a moving magnetic field, moves electrons from the outer shell of an atom. That movement changes the charge balance. Movement of electrons through a conductor continues to take place by using the electrostatic forces of either repulsion or attraction. For example, electrons on a negatively charged atom want to push the extra electron away. Positively charged atoms want to pull electrons onto the atom to balance the number of protons with electrons.

When areas of positive or negative charges are created, a pole, or polarity, is established. **Polarity** is simply the state of charge, either positive or negative. Polarity produces current flow (**FIGURE 9-15**). Electrons always move toward a positive pole and not the other way around. Areas of unbalanced electrical charges create either positive or negative poles (**FIGURE 9-16**). Polarity differences are also called potential differences and produce current flow.

The movement of negatively charged electrons to a positive charge is called the **electron theory of current movement**. It is actually not a theory, but a fact. The idea that electric current movement takes place when positive charges move to a negative pole is called **conventional current theory**. Conventional

FIGURE 9-15 Polarity and electrostatic forces produce current flow.

FIGURE 9-16 The pressure difference between poles produces current flow. The pressure difference is measured in volts.

current theory of electric charge movement was based on a 1910 model of the atom, which was incomplete. Later investigation found this idea was incorrect, and only negatively charged electrons moved in a circuit—in a negative to positive direction.

Many textbooks and training aids still used in trade occupations use conventional theory to explain electrical behavior. Trying to separate electron and conventional theory in practice can become confusing. However, the acceptance and use of either idea is generally not important for the technician. It is only important to remember that current flow is described by both concepts.

Nevertheless, technicians should be aware that some test instruments such as amp volt resistance (AVR) machines are designed presuming current flow is conventional (**FIGURE 9-17**). By contrast, **digital multimeters**, as shown in **FIGURE 9-18**, use electron theory, and the direction of current flow is generally provided by polarity indicators. Connecting the black or common lead of a meter to a positive voltage and the positive meter lead to a negative will cause the meter to display a negative

symbol beside the number in the digital display. Diagnosing an unintended key-off current draw or parasitic current loss is one instance where it is important to note the direction of current flow; electron theory should prevail when trying to understand the problem.

Electron theory is also best used to describe the operation of semiconductors and more advanced electronic devices. Tracing current flow in wiring diagrams, however, is often easier using conventional theory. On circuit diagrams, the movement of current is often traced from the top left corner down to ground connections at the bottom of a page or PC screen.

FIGURE 9-17 An amp volt and resistance (AVR) test instrument.

FIGURE 9-18 A digital multimeter displays electrical measurements in digits rather than using a sweeping needle.

► Direct Current and Alternating Current

K09005

When electrons move only in one direction in a circuit, the current is described as being **direct current (DC)**. In a DC circuit, electrons move continuously from negative to positive (**FIGURE 9-19**). When electrons are alternately pulled and pushed, it regularly changes the direction of current flow. That type of current flow is described as **alternating current (AC)** (**FIGURE 9-20**). When describing alternating current, the term “frequency” is used in addition to voltage and amperage. Frequency is measured by how often the alternating current changes direction. Units for frequency (direction changes per second) are called **hertz (Hz)**, which is another term for cycles per second. Plotting DC voltage on a graph produces a straight line, as shown in **FIGURE 9-21A**. Plotting AC voltage on a graph produces what is called a **sine wave** shape, illustrated in **FIGURE 9-21B**.

DC current flows only in one direction—from a positive to negative pole. A mobile off-road machine and its chassis are an example where DC current flow takes place (**FIGURE 9-22**). High concentrations of extra electrons at the negative polarity battery post travel through chassis ground cables to the machine circuits and electrical devices to reach the positive polarity battery post, which is deficient of electrons. Battery voltage, or potential difference, is determined by the comparing the overconcentration of electrons at the positive post and electron deficiency at the negative post. The greater the difference in electron concentration between the two points, the higher the battery voltage. How much resistance is present in the circuits between the positive and negative posts determines the volume of electrons that can flow—which is another way to describe amperage.

DC circuits are used in virtually all chassis circuits because a battery can easily store and supply DC current. But DC current has one major disadvantage: the farther it travels, the more resistance is present in the circuit. For example, if circuit amperage is high and correct size of wiring is not used, battery voltage can drop from 12.8 volts at a battery to just under 8 volts at the starter.

Alternating Current Flow

FIGURE 9-20 AC current changes direction. The number of times it changes per second is measured in hertz (Hz).

AC current is used to more efficiently power electric propulsion motors. AC current’s main advantage is that it can be transmitted farther distances with less resistance and little voltage drop. Resistance is proportional to the frequency of AC polarity change. That is, the higher AC current’s frequency, the less resistance AC current has in a circuit.

This property of AC current explains why it is used to transmit electricity to homes and industry over long distances with little power loss. Ohm’s law does not apply to AC current flow except through resistors. The term “impedance” is used instead to describe resistance in AC circuits. AC current is a more

FIGURE 9-19 Current flow in one direction only is called direct current. Current flow that continuously changes direction is alternating current.

FIGURE 9-21A Waveforms. **A.** Direct current. **B.** Alternating current.

FIGURE 9-22 Machines use the frame as the ground or negative pole for the electrical system. A negative ground chassis reduces frame and body corrosion. Corrosion is more likely to take place on positively charged wires.

FIGURE 9-23 This variable reluctance sensor (VR) produces AC voltage. The waveform is displayed on a graphing meter.

efficient type of current to power electric motors, and using it simplifies motor construction. The speed of AC electric motors is also regulated by the frequency of AC current—higher frequency translates into faster motor speed.

Alternators produce AC current, which is then changed to DC current inside the alternator by a rectifier. To change DC current to AC current, a device known as a wave inverter, shortened to just **inverter**, is used. A variable reluctance-type sensor, such as the one shown in **FIGURE 9-23**, is used to measure wheel or engine speed and also can produce AC current.

► Heating Effect of Current

K09007, S09002

When an electric current travels through a bulb filament or an electric heating element, the filament or resistive element heats. Resistance in the elements converts electrical energy into heat energy. This observation is referred to as the “heating effect of current.” As amperage and resistance increase, so does the heat produced, as shown in **FIGURE 9-24**.

So, why does the bulb filament heat and glow, but the wires connecting the bulb do not? The simple answer is that the narrowing of the circuit conductor causes collisions to take place between the electrons as they funnel into the circuit’s restriction. Electrons, which are three times the size of protons, convert kinetic energy, present in electric current flow, into heat and light.

To understand this effect, think of a busy highway as traffic merges from six lanes to a single lane. The single lane cannot accommodate all the vehicles, so traffic must slow. Applying brakes reduces vehicle speed, much like voltage drop, and kinetic energy converts to heat due to friction between the brake drums, rotors, and friction material.

Fuses take advantage of this heating effect by using a narrow metal strip made of highly conductive material. When the amount of amperage exceeds a wire’s ability to conduct the current without heating up, the strip melts to protect circuit wiring from burning. The amount of heat produced is directly proportional to the fuse’s resistance, the time current flows, and the amount of amperage in the current. The transformation during heating is measured in joules. Mathematically, the relationship is described as:

$$H = I^2Rt$$

where H is the heat output, I is the current (amps), R is the resistance in the circuit (ohms), and t is the time (seconds). So, if 2 amps pass through a wire with 25 ohms of resistance over the course of 1 minute (60 seconds), then the heat output is 6,000 joules.

Joule’s law refers to the heating effect of electric current. It also helps explain why the seemingly small resistance of narrow wire having 0.01 ohm will drop voltage by only one-tenth with 1 amp of current but will completely burn if 750 amps of current pass through the connection, whereas a 00 gauge battery cable can easily handle the higher current load. The bigger cable with a larger cross-sectional area can conduct more amperage with less resistance because fewer collisions caused by cable narrowing will take place.

► Electrical Versus Electronic Circuits

K09006

Even though electricity is used to operate electrical and electronic circuits, the two types of circuit are not identical. What are the differences between electrical and electronic circuits? Electrical circuits usually conduct higher amounts of current

FIGURE 9-24 Exceeding the nominal amperage limit for a conductor will cause it to heat, and its temperature increases exponentially.

through heavier conductors and commonly operate devices such as solenoids, relays, motors, lights, and more. Electronic circuits use electricity to operate semiconductors such as transistors, integrated circuits, microprocessors, or microcontrollers. Electronic circuits use less amperage and often process electrical signals rather than perform the work of lighting, heating, and movement.

Semiconductors

Semiconductors are the most important type of material used to construct electronic devices. This material can have properties of both conductors and insulators and can switch back and forth between either state using small electrostatic charges. Early semiconductors were made from alloyed materials such as silicon or germanium. A very small quantity of another material added to silicon or germanium gives the new alloyed semiconductor its unique electrical properties.

Most semiconductors today are made from metal oxides. Metal oxide semiconductors are used in MOS-type transistors and microprocessors. MOS types have less resistance and conduct more current than the older semiconductor materials. Field effect transistors made from metal oxides are abbreviated **MOSFET** and are one of the most common types of transistors used in circuit boards by electronic control modules. **FIGURE 9-25** shows a MOSFET transistor.

Transistors can be used to switch current flow on and off and to amplify electrical signals. They are also used to construct logic gates in integrated circuits. Logic gates enable integrated circuits and larger microcontrollers and processors to perform mathematical calculations essential for the proper functioning of an ECM.

Two types of materials make up a basic semiconductor. One is a **P-type material**, which is made from material that can accept electrons. The “P” stands for positive because of its ability to accept and transport electrons. **N-type material** contains loosely held electrons, which explain why it’s called “N,” or negative, material. Both P and N materials are useless on their own, but when placed together, they can form diodes and transistors. Using MOS semiconductors, the material can even be arranged in a chip to function both as a resistor and capacitor which means that almost any type of circuit can be constructed from just this material.

FIGURE 9-25 MOSFETs and other MOS semiconductor devices are used in ECM circuit boards. This is an ECM from a Mercedes MB900 diesel engine, and the MOSFETs are output drivers.

► Wrap-Up

Ready for Review

- ▶ Today, the number of electrical circuits has increased into the thousands, and not a mobile off-road machine system is without electronic control.
- ▶ Electrical system components on mobile off-road machines are no longer separated into distinct systems. Electrical control is distributed over multiple electronic control modules (ECMs). ECMs are connected together to form onboard networks.
- ▶ It may be helpful to think of electricity as nothing more than the movement of specific particles from one point to another. The analogy of electric current flow using the hydraulic model is helpful to understand concepts of voltage, amperage, and resistance.
- ▶ The concept of voltage indicates the speed of electron movement from atom to atom. It is equivalent to the measurement of pressure in a pipe in pounds per square inch (psi).
- ▶ Amperage is a measurement of the number of electrons flowing past one point in a circuit during 1 second. It is equivalent to the measurement of flow or volume in a pipe in gallons or liters per second.
- ▶ Electrical resistance is similar to the idea of friction. Resistance slows down electron speed, which in turn reduces voltage and amperage.
- ▶ Forces of repulsion and attraction between electrons and protons are termed electrostatic force and are the primary type of energy contained in electricity used to perform work.
- ▶ Atoms are made of three fundamental particles: electrons, protons, and neutrons. Positive electrical charges are found on protons, negative charges on electrons, and neutrons have no electrical charge.
- ▶ Poles are areas of concentrated positive and negative electrical charges. Polarity is needed to produce electron flow.
- ▶ Ions are atoms with an imbalance of electrical charges due to the gain or loss of electrons.
- ▶ The flow of electrons from atom to atom is the basic concept of electricity.
- ▶ Current can be described as a function of voltage and amperage in a circuit—in other words, the speed and quantity of electron flow. Without either property, there is no flow of electricity in a circuit.
- ▶ The number of free electrons in an atom's valence ring determines how conductive the atom is. Fewer outer-shell electrons are associated with greater conductivity.
- ▶ Electron theory states that electrons move from negative to positive. Conventional theory states that electrons move from positive to negative. Both theories convey the idea of current flow, and each may in some instances be helpful when performing electrical diagnostic work.
- ▶ Electrical circuits usually conduct higher amounts of current through heavier conductors, and electronic circuits use electricity to operate semiconductors.
- ▶ The two fundamental types of current flow are direct current (DC) and alternating current (AC).
- ▶ Direct current has a constant polarity; alternating current has continuously changing polarity that produces a sine wave.
- ▶ Resistance is measured in ohms and depends on the type of material, its length, diameter, and temperature of the conductor.
- ▶ Good conductors have low resistance, and insulators have high resistance. Electrical energy lost through resistance is converted into heat.
- ▶ Semiconductors combine P-type and N-type materials.
- ▶ Semiconductors are very versatile materials and are used to make various electronic components. Their conductivity can be manipulated and precisely controlled using small electrostatic charges.

Key Terms

Alternating Current (AC) A type of current flow that continuously changes direction and polarity.

amperage The measurement of the quantity of electrons in electric current movement.

ampere (amp) The unit for measuring the quantity or numbers of electrons flowing past one point in a circuit per unit of time.

conductor A material that easily allows electricity to flow through it. It is made up of atoms with very few outer-shell electrons, which are loosely held by the nucleus.

conventional current theory The theory that the direction of current flow is from positive to negative.

digital multimeters An electronic test instrument.

Direct Current (DC) Movement of current that flows in one direction only.

electrical resistance A material's property that reduces voltage and amperage in an electrical current.

electron theory of current movement The movement of negatively charged electrons to a positive charge.

electrostatic theory The idea that like charges repel one another and unlike electrical charges attract.

ground The pathway through the chassis components, rather than insulated wiring for electrical current to move through a machine.

hertz (Hz) The unit for electrical frequency measurement, in cycles per second.

insulator A material that holds electrons tightly and prevents electron movement.

inverter A device that changes direct current into alternating current. Also called a *wave inverter*.

load A device in an electrical circuit with resistance.

MOSFET A field effect transistor made from metal-oxide semiconductor material.

N-type material Semiconductor material able to hold a small amount of extra electrons.

ohm The unit for measuring electrical resistance.

ohm's law A law that defines the relationship between amperage, resistance, and voltage.

polarity The state of charge, positive or negative.

P-type material Semiconductor material having electron deficiency or a place to hold additional electrons.

resistor A component designed to produce electrical resistance.

semiconductor A material that can have properties of both conductors and insulators and that can switch back and forth between either state, using small electrostatic charges.

sine wave The shape of an AC waveform as it changes from positive to negative, graphed as a function of time.

volt The unit used to measure potential difference, or electrical pressure.

voltage The speed at which electrons travel from atom to atom.

Review Questions

- Which of the following statements is correct concerning conductivity?
 - Copper makes an excellent conductor.
 - Electrolytes are liquids that conduct electric current.
 - The liquid inside a lead-acid battery is an example of where electrolyte is used.
 - All of these are correct.
- Which of the following is correct concerning electrostatic law?
 - A proton (+) charge repels another proton (+) charge.
 - An electron (−) charge repels another electron (−) charge.
 - A proton (+) charge attracts an electron (−) charge.
 - All of these are correct.
- Which of the following is *not* correct concerning basic electricity?
 - All matter is made up of atoms.
 - Atoms are composed of electrons, protons, and neutrons.
 - Positive electrical charges are found on protons.
 - Negative electrical charges are found on neutrons.
- Which of the following is *not* a factor that determines the level of electrical resistance?
 - Type of material
 - Length of the conductor
 - Diameter of the conductor
 - Weight of the conductor
- Which of the following is *not* correct concerning movement of electric current?
 - Watts or wattage is the unit for measuring power.
 - Resistance produces a decrease or drop in voltage.
 - Wattage is a function of Voltage $\times$ Amperage.
 - Resistance is measured in amps.
- Which of the following statements about Ohm's law is correct?
 - If voltage is held constant in a circuit: amperage increases if resistance decreases; amperage decreases if resistance increases.
 - If resistance is held constant in a circuit: amperage increases if voltage increases; amperage decreases if voltage decreases.
 - If amperage is to remain the same in a circuit: voltage must increase if resistance increases; voltage decreases if resistance decreases.
 - All of these are correct.
- Which of the following statements is correct concerning semiconductors?
 - Transistors can be used to switch current flow on and off and to amplify electrical signals.
 - Transistors are used to construct logic gates in integrated circuits.
 - Logic gates enable integrated circuits and larger micro-controllers and processors to perform mathematical calculations essential for the proper functioning of an ECM.
 - All of these are correct.
- Which of the following is *not* correct concerning semiconductors?
 - Semiconductors are the most important type of material used to construct electronic devices.
 - Semiconductors can have properties of both conductors and insulators and can switch back and forth between either state, using small electrostatic charges.
 - Early semiconductors were made from alloyed materials such as silicon or germanium.
 - Most semiconductors today are made from platinum or a silicone blend.
- All of the following statements about the heating effect of current and fuses are true *except*:
 - Fuses use a narrow metal strip made of highly conductive material.
 - When the amount of amperage exceeds a wire's ability to conduct the current without heating up, the strip melts to protect circuit wiring from burning.
 - Boyle's law refers to the heating effect of electric current.
 - The amount of heat produced is directly proportional to the fuse's resistance, the time current flows, and the amount of amperage in the current.
- Which of the following statements is correct concerning direct current and alternating current?
 - When electrons move only in one direction in a circuit, the current is described as being direct current (DC).
 - Plotting DC voltage on a graph produces a straight line.
 - Plotting AC voltage on a graph produces what is called a sine wave.
 - All of these are correct.

ASE Technician A/Technician B Style Questions

1. Technician A says there are two theories of current flow: the electron theory and the conventional theory. Technician B says it is only important to remember that current flow is described by both concepts. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says AC circuits are used in virtually all MORE machines circuits because a battery can easily store and supply AC current. Technician B says DC current is used to power hybrid-drive electric motors. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says AC current's main advantage is that it can be transmitted farther distances with less resistance and little voltage drop. Technician B says the term "resistance" is used with AC circuits as well as DC circuits. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
4. Technician A says when an electric current travels through a bulb filament or electric heating element, the filament or resistive element heats. Technician B says resistance in the elements converts electrical energy into heat energy. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says electronic circuits use less amperage and often process signals rather than perform the work of lighting, heating, and moving. Technician B says electrical circuits usually conduct higher amounts of current through heavier conductors and commonly operate devices such as solenoids, relays, motors, lights, and more. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
6. Technician A says metal oxide semiconductors are used in MOS-type transistors and microprocessors. Technician B says MOS types have less resistance and conduct more current than the older semiconductor materials. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
7. Technician A says two types of materials make up a basic semiconductor. Technician B says the two types are R type and M type. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says today's electrical system components are no longer separated into distinct systems. Technician B says networking electrical system components provides the means for new machine features that can enhance safety, performance, and operator comfort. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
9. Technician A says all questions about the nature of electricity lead to the composition of matter. Technician B says the movement of electrons from one atom to another is called electricity. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
10. Technician A says metals typically have lots of easily moved electrons, which make them good conductors. Technician B says liquids cannot function as a conductor. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

CHAPTER 10

Electrical Circuits and Circuit Protection

Knowledge Objectives

After reading this chapter, you will be able to:

- **K10001** Define and describe types of electric circuits.
- **K10002** Describe the relationship between voltage, amperage, power, and resistance in electrical circuits.
- **K10003** Identify and describe the types and causes of electrical circuit failures.
- **K10004** Identify and describe types of circuit protection devices.
- **K10005** Identify and describe the operation of relays, magnetic switches, and solenoids.

Skills Objectives

After reading this chapter, you will be able to:

- **S10001** Inspect and test circuit protection devices.
- **S10002** Identify a resistive ground connection.

► Introduction

Circuits are pathways made by electrical conductors that enable the flow of electrons. A variety of classifications are used to describe circuit configurations and failures. Most important for technicians to understand is how circuits are constructed. With that knowledge, a technician can properly analyze electrical problems, use correct diagnostic procedures with test instruments, and, of course, make accurate recommendations for repair, rather than guess at what may be wrong.

As shown in **FIGURE 10-1**, circuits consist of the following basic parts:

- Power source—in the form of a battery or alternator.
- Conductors—paths for electricity (e.g., wiring, printed circuits, chassis frame).
- Loads—the working devices that turn electrical energy into some other form of energy, such as lamps (light), motors (kinetic), radio (sound), glow plugs (heat), and more. Loads are considered the resistance of a circuit.
- Control—a device, such as a switch, that directs the flow of electrons through the circuit.
- Safety/circuit protection devices—fuses, circuit breakers, and virtual fuses, which protect the electrical system by interrupting the flow of current if the current flow becomes excessive.

FIGURE 10-1 Minimum elements of a circuit include a power supply, circuit protection, control, and load.

► Circuit Classification

K10001

Circuits found in mobile off-road equipment are classified three ways:

1. Operational state—open or closed
2. Arrangement—simple, parallel, series, combination
3. Failure mode—grounded, shorted, open, resistive, and intermittent circuit malfunctions

Operational State

“Open” and “closed” are the terms used to describe whether current is flowing through a circuit. An open circuit’s electrical pathway is broken or unconnected (**FIGURE 10-2A**). This means current cannot flow because there is an open gap between two ends of the circuit. Current cannot move across the gap until the opening is closed.

A closed circuit has a complete electrical pathway for current to flow between the negative and positive terminal, as in **FIGURE 10-2B**.

► TECHNICIAN TIP

Sleep or hibernation mode is a related term given to electronic control modules to describe a state where current flow is reduced after the ignition key is switched off or after a predetermined length of time has elapsed. Sleep mode reduces prolonged current drains from the battery.

Circuit Arrangement

Electric circuits are also classified according to the way electric components and loads are connected. Circuits on mobile off-road equipment are made from these types of arrangements:

- Simple
- Series

You Are the Mobile Heavy Equipment Technician

A motor grader has arrived at your shop with the request to install a wave inverter to enable the operator to charge cell phones and tablets and use laptop computers. The company wants you to supply 120 volts AC to a receptacle. Upon inspection, you find that the machine is equipped with a split voltage electrical system with a 24-volt alternator used to charge the batteries and supply the starter motor. An isolated ground is used on the rest of the motor grader, which uses 12 volts for all lights and accessories outside the engine compartment. When you ask the company representative what amount of amperage the company wants to supply the receptacle, the representative asks you to make a recommendation.

After researching the problem, you learn that the heaviest power users would be laptops consuming 3–5 amps to charge a dead battery. As you prepare quotes and recommendations for supplying the DC–AC converter, wiring them, and providing circuit protection to the inverters, you will need to consider the following:

1. What would be the maximum wattage required for the inverter? Assume there is no heat or other losses of electrical energy.
2. What would be the minimum fuse rating for the inverter using a single positive conductor if they were supplied either 12 or 24 volts?
3. What would be the minimum size of the conductors required if the inverters were connected to either a 12- or 24-volt power supply?

FIGURE 10-2 **A.** An open circuit has a broken electrical pathway. **B.** Closing the switch completes the electrical pathway.

- Parallel
- Series-parallel, also called combination circuits

Simple circuits are circuits that have only a power supply and a load. These are not used in mobile off-road equipment. This section, therefore, concentrates on series, parallel, and combination circuit arrangements.

Series Circuits

Series circuits are the simplest of circuits. In a **series circuit**, there can be multiple loads, but only one path for current to flow (**FIGURE 10-3**). Each device is connected like a chain, with all current flowing through one device after another. The defining characteristic of a series circuit is that only one single pathway exists for current to flow. The conductors, circuit protection device, loads, and source current are connected together, allowing current to move—but only through one path. If any part of the circuit is opened, such as when a lightbulb burns out, all current flow through the circuit stops.

The following features characterize series circuits:

- Only one single pathway exists for current to flow.
- The resistance of each load or device may vary, but the amount of current flowing through each will be the same.

The sum of the voltage drop across all loads is equal to the source voltage. This means all the voltage is used up pushing electrons through the loads. This observation is referred to as **Kirchhoff's law** and is illustrated in **FIGURE 10-4**. The voltage

drops across each of the loads will change if the resistance of the device or load is different from the others.

- At any given point in the circuit, the amperage is the same.
- The total circuit resistance is equal to the sum of each individual resistance.

Many machine circuits are series circuits. Switches, terminals, circuit protection, cables, and so on are common circuit components arranged in series (**FIGURE 10-5**). Identifying problems in series circuits often becomes a matter of measuring voltage drops to locate poor connections and deteriorated or defective components (**FIGURE 10-6**). A starter cable voltage loss test is one example of a test procedure using series circuit electrical principles to locate problems causing slow cranking. Excessive resistance at a starter cable connection due to corrosion will create a voltage drop and reduce the available voltage for the starter motor which results in slow cranking.

A starter motor circuit is a more complex example of a series circuit. Current passes from the chassis ground, the brushes, and field coils of the motor before entering the solenoid and then returning back to the battery. An open brush or coil will prevent the starter motor from turning because it is a series circuit.

Parallel Circuits

A more complex circuit than a series circuit arrangement is a **parallel circuit**. In a parallel circuit, there are multiple pathways for current flow, and all components are connected directly to

FIGURE 10-3 Observations for series circuits.

FIGURE 10-4 Voltage drop is the loss of voltage or electron pressure as current passes through a load. A voltmeter is used to measure the drop. Voltmeters measure a circuit's electron pressure differential. Note all the voltage is dropped after passing through the loads in a circuit.

FIGURE 10-5 An example of how voltage drop testing can be used at various points for a starter circuit.

FIGURE 10-6 Understanding the behavior of voltage, amperage, and resistance in a series circuit. With each resistance, the voltage (electron pressure) drops. The voltage drop is cumulative and distributed across all the loads. Amperage (volume) in the circuit is dependent on total of circuit resistances. The amperage remains constant anywhere in the circuit.

FIGURE 10-7 Parallel circuit with two loads that have different resistances and that create different current flows in each branch. Total flow is the cumulative of all parallel branch current flows.

the voltage supply. On paper, the schematic diagram of a parallel circuit resembles a ladder. The sides are sources of voltage—one is positive and the other negative. The ladder rungs are called branches. Because all branches connect to the same positive and

FIGURE 10-8 An example of a parallel circuit. Bulbs **A** and **B** are branches of the circuit.

negative current source, amperage in each branch can be different, depending on the branches' resistance. Adding the amperage in each branch will equal the total amperage in the circuit (**FIGURE 10-7**). Adding loads, however, lowers circuit resistance; the total resistance is always less than the smallest resistance in any branch.

In summary, a parallel circuit is characterized by the following:

- There are two or more pathways for the current (**FIGURE 10-8**).
- The voltage applied to each branch is the same throughout the circuit (**FIGURE 10-9**).

FIGURE 10-9 All loads in a parallel circuit receive the same voltage. The amperage used by each branch varies with the resistance in each branch.

FIGURE 10-10 Amperage passing through each branch of a parallel circuit varies with the resistance.

- Amperage flow through each branch depends on its resistance. If the resistances in each branch are the same, the amperage will be the same.
- If one branch of the circuit is broken, current will continue to flow in the other branches.
- Total circuit resistance is always less than the resistance of the smallest resistor (**FIGURE 10-10**).

Lighting circuits are common examples of parallel circuits. Machine work lights or taillight circuits are all connected in parallel with battery voltage applied to each bulb. Adding more lights creates more pathways for current to flow. This means amperage consumed in a parallel circuit will increase with every additional load (**FIGURE 10-11**).

Combination Circuits

Combination circuits, also called **series-parallel circuits**, use elements both of parallel and series circuits. These circuits are the most common ones used in mobile off-road machines. Typically, the power and control circuits are in

series, but the loads are in parallel. When calculating or measuring voltage, amperage, and resistance, the rules for parallel and series circuits apply to each part of the circuit. That means the circuit must be subdivided into series and parallel circuits, and then calculations can be performed for each type of circuit.

► Current Flow in Circuits

K10002

Electrons making up current flow are not magically created by the circuit or power source. Only the electrons found in the conductors of a circuit move in a circuit. That means only the electrons already present in conductors, electrolyte, or devices of the circuit are put in motion. An analogy using a closed hydraulic system with a water pump shows that only electrons already present in the circuit are flowing (**FIGURE 10-12**). Consider hydraulic fluid that is pulled from a reservoir and put into motion. Fluid pressure and flow determine how much power the system has. Eventually the fluid pushed out the pump outlet returns to its inlet to keep the flow going. In the same way, electrons are pulled and pushed through conductors and loads in electric devices. The negative terminal pushes electrons, using electrostatic forces of repulsion, and the positive terminal pulls electrons by forces of electrostatic attraction. In a machine's electrical system, an alternator performs the same function as the fluid pump.

Resistance

Resistance refers to the force in a circuit that impedes or slows the transfer of electrons from one atom to the next. Explained another way, resistance is electrical friction. Resistance will lower both voltage and amperage in a circuit in proportion to the amount of resistance. Ohm's law mathematically describes the electrical relationship between voltage, amperage, and resistance.

FIGURE 10-11 Comparing a hydraulic model of a parallel circuit with a schematic version. Note the same pressure is applied to all circuit branches, and the voltage drops to almost zero after passing through the loads.

FIGURE 10-12 Current flow in a circuit is like a closed hydraulic system. Just as no new fluid is created in a hydraulic system, the conductors in the circuit are the only source of electrons. Loads use the energy in the flowing water and convert it to another form such as motion, sound, light, and heat.

► TECHNICIAN TIP

Technicians rarely ever need to use an electrical formula to diagnose and repair a problem on mobile off-road equipment. And most instructors would agree that it is rare to perform mathematical calculations in the average repair facility. So, the question that naturally follows this observation is this: What is the point of learning formulas or performing calculations while learning about electrical systems? It is simply this: mathematics is another language that is effective in describing the behavior of electricity. Many learners who have struggled to understand electrical concepts have quickly grasped important insights while doing calculations using formulas based on electrical laws. Math is very often a shortcut to better comprehension of electrical subject matter.

Ohm's Law

Ohm's law defines the relationship between current, resistance, and voltage. Ohm's law calculations are seldom used by a technician, but comprehending the law's principles can help you better understand how electricity behaves. Working through calculations using Ohm's formula also enhances your intuitive understanding of electricity, which is invaluable when troubleshooting electrical circuits. The tradesperson's triangle in **FIGURE 10-13** is used to help calculate the values of voltage, amperage, or power. Placing your finger over the unknown value will help you determine whether the other two values should be multiplied or divided.

Ohm's law explains in mathematical language the relationship between amperage, voltage, and resistance in a circuit.

$$\text{Voltage} = \text{Amps} \times \text{Resistance}$$

Simply stated, 1 volt is required to push 1 amp of current through a circuit that has a resistance of 1 ohm. Ohms Ω are the unit used to measure resistance (**FIGURE 10-14**).

One application for Ohm's law is to calculate the voltage drop in a conductor for taillight wiring. All conductors have some resistance, so there will be a voltage drop through the wires going to the taillights at the rear of the machine. The amount of the drop depends on the amperage flowing through the circuit and the resistance of the wiring and connections. **TABLE 10-1** summarizes recommended wire gauge size required to minimize voltage drop.

Watt's Law

Watt's law, which is related to Ohm's law, explains the relationship between power, voltage, and amperage (**FIGURE 10-15**). Mathematically described, Watt's law is:

$$\text{Power (Watts)} = \text{Voltage} \times \text{Amperage}$$

With a constant system voltage, an increase in amperage through a circuit produces proportionally more power.

Heat is generally an unwanted by-product of resistance. Heat is produced as electron energy is lost due to resistance. Collisions occurring between electrons as they converge at "choke points" or resistive parts of a circuit produce heat. Increasing the amperage in a circuit is something like increasing the number of cars on the highway during rush hour—the greater the number of cars, the slower the traffic. More collisions between electrons take place in a crowded conductor, and electron energy is converted to heat.

This relationship between amperage and resistance explains why a thin wire can carry low-amperage current but would burn up (or at least overheat) if it were carrying excessive amperage. Excessive amperage through terminals and connectors produces heat, which in turn loosens electrical connections due to temperature cycling. Resistance in connections at the battery or

Ohm's Law states: Voltage = Amperage x Resistance

Arrange the variables into a "Tradesperson Triangle"

By covering up the unknown it is easy to transpose the formula.

FIGURE 10-13 The tradesperson's triangle for calculating power.

FIGURE 10-14 The relationship between volts, ohms, and amperage in Ohm's law.

in a starter motor circuit, which are undetectable with an ohmmeter, will show up as heat when a starter is cranking or when heavy loads are switched on in a machine. The most effective way to measure resistances in these circuits is to perform a voltage drop test when the high-amperage circuits are operating. Resistance will show up as voltage loss across resistive connections and components.

Advantages of the 24-Volt System

The 24-volt electrical systems used by many mobile off-road equipment machines have several advantages. First, by using

TABLE 10-1 Recommended Wire Gauges to Minimize Voltage Drop

Amperage	10 – Feet Gauge	20 – Feet Gauge	30 – Feet Gauge	50 – Feet Gauge	100 – Feet Gauge

P = Power measured in WATTS
 A = Amperes measured in AMPS
 V = Electromotive Force measured in VOLTS

FIGURE 10-15 The relationship of power, voltage, and amperage according to Watt's law.

FIGURE 10-16 Electric motors are examples of constant power devices.

higher voltage, less amperage passes through a circuit to produce the same amount of power as a 12-volt circuit. For example, a device needing 120 watts of power would use 10 amps at 12 volts (Power = Amperage $\times$ Voltage). Electric motors are examples of constant power devices (**FIGURE 10-16**).

This means the number of watts they use to maintain speed is the same if circuit voltage and amperage change. For example, a 96-watt blower motor that is part of a 12-volt system has 8 amps flowing through it (Power = Volts $\times$ Amperage). At 24 volts, only 4 amps are required.

Reducing amperage through a circuit not only reduces resistance but also the size of conductors. Voltage drops in the system are reduced as well. More importantly, operating at 24 volts in comparison to at 12 volts gives an electrical system greater reliability. That is because heating and loosening of electrical connections are minimized. Finally, the size of components can be reduced, with increased power supplied by 24 volts (**FIGURE 10-17**).

FIGURE 10-17 Many mobile off-road machines use 24-volt systems because of longer runs of wire and the greater use of electrical accessories such as lighting and ventilation. Voltage drops and electrical system problems due to high current flow are minimized. **A.** A battery equalizer allows voltage to split between 24-volt and 12-volt devices. **B.** A batter equalizer.

► Circuit Malfunctions

K10003

Just as there are categories for operational circuits, defective circuits have names based on failure mode. Classification of circuit malfunction can include the following:

- Opened
- Shorted
- Grounded
- High resistance
- Intermittent

Open Circuit Faults

When a circuit defect is caused by an opening in the electrical pathway, no current can flow through the circuit and this is considered to be an open circuit. Open circuits can be caused by a variety of problems, including poor ground or terminal connections, defective switches, and broken wiring (**FIGURE 10-18**). A fuse or circuit breaker that has opened due to excessive current flow creates an open, but the root cause of the problem is not the fuse.

FIGURE 10-18 Causes of open and intermittent circuits.

Where the open in the circuit occurs determines how the failure presents itself. For example, a broken wire to a single clearance light in a parallel circuit will have a different effect than a blown fuse. Depending on the type of fault, open circuits are typically detected using a multimeter or advanced test light to look for available voltage along the circuit (**FIGURE 10-19**).

FIGURE 10-19 More advanced test lights are battery powered. Single probe tip can be used to determine polarity and detect ground, power, shorts, and breaks. Red LED indicates power; green LED indicates ground.

High-frequency radio waves can be used to identify faults in bundles of wiring or in long runs of wiring hidden behind panels. A radio transmitter (**FIGURE 10-20**) installed in the fuse of an open or shorted circuit will emit short bursts of radio signals

FIGURE 10-20 **A.** Radio receiver. **B.** Radio transmitter. **C.** This radio signal generator is designed to find opens, shorts, or grounded circuits without damaging the wire. A high-frequency signal is added into the circuit by connecting a transmitter. Moving the receiver in the vicinity of the wire will locate the break.

or low-voltage current into the defective circuit. The signal is not powerful enough to damage wiring, but open and shorts are located using a handheld radio receiver. A schematic diagram is useful when identifying open circuits to locate strategic points where circuit voltage can be measured using a multimeter. An ohmmeter can be used to find points where circuit continuity is lost only after the system is de-energized.

In onboard diagnostic system (OBD) circuits, the continuous component monitor constantly checks for open circuits by comparing signal out and return voltages.

Short Circuits

Short circuits are commonly thought of as the unwanted, high-amperage flow between battery power and negative ground. However, that type of fault is better described as a grounded circuit or short to ground. As its name suggests, a short is an electrical circuit that is formed between two points that bypasses the original current path, allowing current to flow through an unintended pathway (**FIGURE 10-21**). The current in a circuit will always try to find the path of least resistance.

A short may draw a higher or lower than normal amperage and simply be an unintended connection between two wires or

circuits. A coil of wire (like one used in a solenoid or motor) is considered shorted if current does not pass through all the intended loops, but instead takes a shorter path. Another simple example of a short to power is a short between the brake light and running lights circuits. Stepping on the brakes would cause the running lights to illuminate, and vice versa. Some may call this a problem with current “backfeed,” but it is more accurate to call it a short.

Onboard diagnostic systems that continuously monitor electrical signals from sensors and output devices will detect shorted conditions too. For example, if a three-wire sensor signal circuit is shorted to +5 volt reference voltage, it meets conditions required to generate the fault code “Sensor Input Voltage High” (**FIGURE 10-22**). The fault description “Sensor Input Voltage Low” is produced if either the sensor +5 volt supply is shorted to the sensor return circuit or the sensor signal wire is shorted to the sensor return circuit or to ground.

Grounded Circuits

A **grounded circuit**, sometime called a “dead short,” is characterized by an unwanted low-resistance connection between battery positive power and chassis ground. Unlike the short-to-power malfunction, in all cases the short-to-ground will draw higher than expected current. A common example of a grounded circuit would be a battery or power cable insulation rubbing through against the negative ground chassis frame (**FIGURE 10-23**). The direct, low-resistance connection would cause high current flow resulting in blown fuse links and activation of other circuit protection devices or in the case of the battery cable rubbed through it could cause a fire due to the tremendous amount of current flowing through the cable.

High-Resistance Circuits

All circuits have a specific amount of resistance in them when new. High-resistance faults occur when the amount of resistance

FIGURE 10-21 When current bypasses its intended load, it is referred to as a short circuit.

FIGURE 10-22 Sensor signal circuits are monitored by the onboard diagnostic system, which continually evaluates electrical system operation. Short circuits generate fault codes such as shorted high or low, or input voltage high or low.

FIGURE 10-23 A grounded circuit fault occurring at a point after the protection device, but before the circuit load, results in an unintended low-resistance path to chassis ground. If the fuse or circuit breaker quickly opens when the control switch is closed, a grounded circuit is likely the cause.

increases above its originally intended value. When grounds or power connections in circuits have excessive resistance, circuits cannot function properly. These circuits can be referred to as being resistive. Circuits will also not operate properly if circuit components become excessively resistive. Dirty, corroded, or loose connections result in **resistive circuits** that do not allow components to properly operate. Battery terminals, lightbulb sockets, and connector sockets are common points for resistances to develop.

High current flow through a connection or circuit that has almost no resistance can turn highly resistive if high amperage passes through the connection.

Resistive ground connections can often be difficult to troubleshoot because circuits will find alternate grounds, or components will operate in very unusual ways. Double filament combined stop/tail bulbs are one common example of what is sometimes called a “backfeed” due to resistive grounds (**FIGURE 10-24**). A poor ground in the bulb socket of one lamp will cause the current to find a ground through the bulb on the opposite side of a machine. The taillights will flash alternately when the turn signal is on, and other bulb filaments will glow dimly even when they should not (**FIGURE 10-25**).

Intermittent Circuits

Intermittent circuits are characterized by an irregular interruption of current flow. Intermittent current flow through circuits is often attributed to vibration from a moving machine. An example is the connectors on the engine ECM, which receives a lot of vibration and has the strain of heavy wiring harnesses. Heat at terminal connections can cause continuous thermal cycling, and engine vibration can contribute to a momentary loss of continuity through a pin connection.

Overheated modules and coils are often another source of intermittent circuit problems. Heat causes resistance to climb in semiconductor devices as well as magnetic coils in solenoids or relays. If, after allowing modules or coils to cool, the devices or circuits operate, these heat-sensitive resistive components should be replaced.

FIGURE 10-24 A poor ground is one cause of a resistive circuit.

FIGURE 10-25 A resistive ground at the left 3157 stop/taillight bulb will cause a current to flow through the right bulb filaments as the circuit seeks a ground. The right bulb filaments will glow dimly because the circuit becomes a series circuit.

► Circuit Protection Devices

K10004

High-amperage flow through circuits produces resistance-induced heat. If excess amperage is allowed to pass through conductors, they can become overheated to the point where the insulation melts, and a fire can result. Circuits overloaded with current-hungry components or grounded circuits are the quickest way to cause damage to wiring and even start fires. So, to protect wiring harnesses and the safety of the machine's operator, circuit protection devices are used. A second reason for circuit protection is because damage to sensitive electronic components can also be caused by unintended reversal of battery polarity, such as when using booster cables. Third, excessive charging system voltage can also push more current through these devices and destroy them.

Traditional fuses, fuse links, and circuit breakers are connected in series and use heat produced from excessive current flow in faulty circuits to open the circuits. Fuses and circuit breakers will open overloaded circuits when amperage typically exceeds 10–15% of the fuse rating. This means a 20-amp fuse will open at 22–23 amps of current. Recently, network control of the electrical system in late-model equipment has

enabled software control of current flow through circuits, introducing what is called the virtual fuse—circuit protection without a fuse.

Thermal Fuses

Thermal fuses come in many configurations (FIGURE 10-26). Three basic types of fuses are currently in use, which are opened by heat produced from resistance caused by high-amperage flow:

- Cartridge type
- Blade type
- Inline type

Cartridge fuses use strips of metal made in various thicknesses that are enclosed in a glass tube. The metal is manufactured to melt at a low temperature. If excessive current flows through the circuit, the fuse element melts at specific amperage due to the calibrated thickness of the metal strip. When inspecting the fuse to see whether it is blown, a break in the metal strip is observed in open fuse. A multimeter should read system voltage when both sides of an intact fuse are probed and the ignition switch is on. Cartridge fuses are seldom used on newer equipment.

FIGURE 10-26 Fuses come in many configurations.

Blade or spade-type fuses have blade-like metal lugs connected by a fusible metal wire. The compact, transparent plastic body allows more fuses to be inserted into a fuse carrier. There are two categories used: ATO and ATC series. The difference is whether the metal fuse wire is sealed or not. It is easy to check the integrity of the metal fuse wire using a multimeter set to DC volts to probe the metal spade ends. These are accessed from the back of the fuse. Breaks in the fuse wire are also visible through the transparent plastic body. Spade fuses are found in a variety of sizes and color-coded as well as numbered to indicate their maximum rated amperage (FIGURE 10-27).

Inline fuses are connected in series with the electrical devices needing additional circuit protection. A device may already be connected in a protected circuit but may have a lower tolerance for overcurrent or reverse polarity conditions. Electronic control modules (ECMs) are a common example of devices with inline fuses protecting the constant battery voltage supply line and supply of current from the ignition switch (FIGURE 10-28).

Low-amperage fuses are easily blown in overcurrent and reverse polarity conditions due to internal circuits using Zener diodes. These diodes allow supply current to go to ground under abuse conditions. Inline fuses are also used when adding electrical accessories to a circuit. Locating the fuses as close to the devices as possible shortens the time needed to blow the fuse. TABLE 10-2 provides the recommended maximum fuse ratings for the corresponding wire size (per the American Wire Gauge [AWG] system).

Major Harness Protection

Fuses are used to protect individual circuits, but not necessarily major wiring harnesses. For those, fusible links are used. Fuse links are short sections of wire installed in series with larger diameter conductors. At one-quarter of the gauge of the main conductor, the fuse link will overheat and melt instead of the larger conductor when excessive amperage passes through the wire. This means brief overloads are possible with fuse links without causing current disruptions. Special plastic covers the link and will bubble when the link melts. Fuse links are effective

FIGURE 10-27 Thermal fuse types—mini, ATC, maxi, and AMG. Fuses are color coded to designate the maximum current.

FIGURE 10-28 Fuses at the battery box are usually protecting the power circuits to the engine ECM.

TABLE 10-2 Recommended Maximum Fuse Ratings by Wire Gauge

Wire Gauge (AWG)	Recommended Maximum Fuse Rating
00	400 amps
0	325 amps
1	250 amps
2	200 amps
4	125 amps
6	80 amps
8	50 amps
10	30 amps
12	20 amps
14	15 amps
16	7.5 amps

protection in major harnesses because limiting amperage in harnesses is not as critical as protecting them from overheating and burning.

Glow plug circuits, alternator battery cables, and major cab harness cables are a few examples where fuse links were once used. Fuse links are checked with a multimeter set to DC volts or by simply pulling the conductor where it usually attaches to a major battery terminal or starter cable connection. A link that stretches excessively like a rubber band is likely melted. Current should be found on both sides of an intact link if checked with a multimeter.

Maxi fuses have replaced fuse links as circuit protection devices. The use of power distribution boxes has broken down machine electrical systems into smaller and more numerous sections using shorter runs of wiring (**FIGURE 10-29**). It is easier to replace maxi fuses found inside distribution boxes, typically in sizes from 20 to 80 amps, which can protect several circuits. Larger specialized ratings are available from OEMs.

FIGURE 10-29 Power distribution boxes are the main location for circuit protection. The boxes break the electrical system into smaller and more numerous sections. Large electrical conductors do not pass through the occupant compartment, where potential fires can occur.

A. Cover with component locator. **B.** Relays. **C.** Insulated positive cables. **D.** Blade-type fuses.

SAFETY TIP

When replacing blown fuses and circuit breakers, never install one with a higher amp rating. This could cause a wire or component to overheat and possibly cause an electrical fire. If a breaker or fuse is operating in an overloaded circuit, replace the wiring with a larger diameter, and then increase the rating of the circuit protection device.

Circuit Breakers

Circuit breakers are used in circuits where intermittent current overloads are common and where power must be rapidly restored, such as with wipers, headlights, and other lighting circuits. Unlike fuses, circuit breakers do not require replacement when they trip. Instead, they may either automatically reset or require a manual reset.

Typically, circuit breakers are made from bimetallic contacts connected in series with a circuit. These are strips of metal made from two different materials with different rates of expansion. When heated, the bimetallic strip bends and opens the contacts, disconnecting current flow from the circuit. Heat is produced when too much current flows through the bimetallic strip in the circuit breaker. In **Type 1 circuit breakers**, or automatically resetting breakers, current is restored when the bimetallic strip cools (**FIGURE 10-30**).

A circuit breaker can be a noncycling type too. Typically, those are **Type 2 circuit breakers**. One type is reset by removing the power from the circuit. A heating coil connected in parallel with the contacts is wrapped around a bimetal arm, keeping the arm hot and contacts disconnected after it has

FIGURE 10-30 Three types of circuit breakers: **A.** cycling, **B.** noncycling, and **C.** manual reset. Bimetal strips of metal with different expansion rates bend when heated. Heat produced during high current flow causes contacts inside the breaker to open to protect the circuit wiring from overheating.

tripped. This current is not enough to operate a load, but the coil does continue heating the bimetal arm until power is removed. Another noncycling breaker is the **Type 3 circuit breaker**, which must be reset by depressing a reset button. The reset button pushes a spring back into position. That spring force holds the bimetal contacts open after the breaker has tripped. **TABLE 10-3** shows this classification for circuit breakers.

PPT Coefficient Fuses

A **polymeric positive temperature coefficient (PPTC) device**, commonly known as a **resettable fuse**, is a thermistor-like electronic device used to protect against circuit overloads. These devices are similar to nonlinear PTC thermistors. When heated while conducting excessive current, however, they quickly cycle between a conductive and nonconductive state until after current is removed or the device has cooled (**FIGURE 10-31**). Resistance in the device will suddenly increase to thousands of ohms.

Current trip ratings for PPTCs range from 20 mA to 100 A. Dozens of these devices are used in a single electrical control module to harden them against damage from shorts to power or ground, as well as other electrical faults in the external circuits they control.

Virtual Fuses

E-fuses are a more recent innovation in circuit protection. **E-fuses**, or **virtual fuses** as they are sometimes called, are software-controlled fuses that use **field effect transistors (FETs)**

FIGURE 10-31 **A.** When heated while conducting excessive current, PPTCs quickly cycle between a conductive and nonconductive state until after current is removed or the device has cooled. **B.** Surface-mount resettable PTCs are used in this injector drive module. The fuses protect the sensitive microcontrollers against grounded circuits, reverse polarity, and electromagnetic interference.

TABLE 10-3 Classification of Circuit Breakers	
Type 1	Automatically resetting—Will cycle the circuit breaker on and off until the overload condition is removed.
Type 2	Modified Type 1—Keeps the circuit breaker open until the overload condition is removed.
Type 3	A manual resetting thermal non-cycling circuit breaker—Remains tripped until the operator manually resets it by pushing a button located on the breaker.

FIGURE 10-32 One of many types of FETs that can conduct high current flow with very little heating. By regulating the current applied to the gate, the amperage through the FET is controlled. Software enables programming of FET capabilities to act as virtual fuses or e-fuses.

for the circuit control device. The development of virtual fuses is important because it saves not only the cost of the fuse but also that of the fuse holder as well as the largest cost associated with using a traditional fuse—the wiring to and from the fuse.

Virtual fuses are now used in most power distribution modules in multiplexed electrical systems to enable programmable limits of amperage to body builder-installed circuits and any other machine circuits. Combinations of two FETs are used along with a signal from a microcontroller to establish a threshold for current transmission (**FIGURE 10-32**). These fuses are reset either when the ignition switch is turned off or when the FETs have sensed the overcurrent condition has ended.

► Inspecting and Testing Circuit Protection Devices

SI0001, SI0002

Protection devices are designed to prevent excessive current from flowing in the circuit. Protection devices such as fuses and fusible links are sacrificial, meaning that if excessive current

flows, they will fail and must then be replaced. Circuit breakers can be reset. Once they trip, they either reset automatically or require a manual reset by pushing a button or moving a lever.

Fuses, fusible links, and circuit breakers are available in various ratings, types, and sizes, and must always be replaced with the same rating and type. In most machines, protection devices are located in the power battery positive side of the circuit. A blown or faulty fuse can be tested using a multimeter or test lamp. A good fuse will have virtually the same voltage on both sides. A blown fuse will typically have battery voltage on one side of the fuse and 0 volts on the other side. Fuses can also sometimes be visually inspected. This may require the removal of the fuse from the fuse holder. The fusible metal strip should be intact and, if measured by an ohmmeter, should have no, or very low, resistance. The contacts on both the fuse and the fuse holder should be clean and free of corrosion and should fit snugly together. To inspect and test circuit protection devices, follow the guidelines in **SKILL DRILL 10-1**. To identify a resistive ground connection, follow the steps in **SKILL DRILL 10-2**.

► Relays, Magnetic Switches, and Solenoids

KI0005

Electrical circuits commonly use relays, magnetic switches, and solenoids as control devices to control the flow of current through a circuit.

Relays

A relay is a switch that uses a small amount of current to switch a larger amount of current. Locating a relay closer to a load requiring large amounts of current eliminates voltage drop caused by resistance from long runs of wires. Relays also eliminate the use of heavy conductors inside the cab of a machine, and that allows for safer operation.

SKILL DRILL 10-1 Inspecting and Testing Circuit Protection Devices

1. Identify the protection device to be inspected and tested. A fuse or circuit breaker is most commonly checked at a power distribution box or fuse panel.
2. Turn the ignition switch to the run or on position to supply power to the fuse.
3. Using a multimeter set to DC volts, probe the fuse or circuit breaker on each side (supply and load) to determine whether current is supplied to the device and whether current is available to the loads in the circuit.
4. If there is only power available to the circuit protection device and not to the load, the device is open. This requires replacement if it is a fuse or resetting the circuit breaker if possible. Fuse replacement is performed after identifying the cause for the overloaded circuit.

SKILL DRILL 10-2 Identifying a Resistive Ground Connection

1. Locate a suspected ground connection. This is usually a bolt on a chassis or terminal on a wire lead attached to a stud.
2. Using a multimeter set to DC volts, place one lead of the voltmeter onto the chassis ground.
3. Place the other lead on the ground connection to the device that is not operating correctly.
4. Energize the device or operate the circuit.
5. If no fault exists, there should be no voltage displayed.
6. A reading of 0.5 VDC for a 12-volt system and 1.0 VDC for a 24-volt system indicates excessive resistance between the two leads of the multimeter.

FIGURE 10-33 Operation of a relay with a single contact. **A.** Nonenergized with contacts open. **B.** Energizing the electromagnet with a small amount of electrical current closes the contacts, which can switch high-amperage current flow.

A typical relay has a control circuit and a load circuit. The control circuit is supplied current through a switch, which often is opened or closed by an ECM or the machine operator. Inside the relay, an electromagnetic coil pulls a set of contacts closed. It is across these contacts that a larger amount of current is switched. The relay's control circuit can be switched by supplying a power or ground to the relay. If an ECM supplies a positive voltage to control the relay, it is termed a pull-up circuit. If it supplies a ground, it is called a pull-down circuit.

International Organization for Standardization (ISO) relays, also called mini-cube relays, are the most common relays used today. See **FIGURE 10-33** and **FIGURE 10-34**.

The relay is standardized to be used across all equipment manufacturers, having standard pin numbers, functions, and dimensions to fit into a power distribution box. These can switch as much as 35 amps in a 24-volt system.

Because relays use electromagnetic coils, a large voltage spike is produced when the coils are de-energized. See **FIGURE 10-35** and **FIGURE 10-36**.

The rapidly collapsing magnetic field will move across the coil conductors, inducing over 200 volts. If the relay control

circuit shares a voltage supply with the ignition switch or sensitive electronic component, electrical damage can occur. To prevent this, a diode or resistor connected in parallel across the

FIGURE 10-34 Mini ISO relays in a power distribution box. Current suppressed relays use a diode, resistor, and sometimes a capacitor to minimize a voltage spike produced through self-induction.

FIGURE 10-35 Self-induction inside a relay can supply a large voltage spike, which can damage sensitive electronic components. No conduction takes place through the diode during normal operation. High-voltage current moving in the opposite direction of the original current will forward bias the diode, and current dissipates through resistance in the circuit.

FIGURE 10-36 A resistor or a diode is used to suppress voltage spike produced through self-induction.

coil will provide an alternate pathway for the voltage spike to dissipate when the magnetic field collapses.

Magnetic Switches

Magnetic, or “mag,” switches are identical in function to relays except that they switch even larger amounts of current and have atypical dimensions. See **FIGURE 10-37**.

Magnetic switches are also classified as continuous or intermittent duty service. When switching heavy amounts of current, such as to the starter motor solenoid, available battery voltage can drop. See **FIGURE 10-38**.

Low available voltage will reduce the magnetic field strength in the switch, causing the relay to “chatter” as it rapidly engages and disengages when the electrical system voltage drops.

To counter this effect, the electromagnetic coil windings are wound from heavier gauge wire. The result is fewer

FIGURE 10-37 Construction of a larger magnetic switch used for switching large amounts of electrical current.

FIGURE 10-38 A. A magnetic switch used to switch high current flow to the **B.** starter solenoid. The chassis ECM supplies a ground to energize the control circuit.

coils but more amperage through the low resistance coil, which helps maintain magnetic field strength, as shown in **FIGURE 10-39.**

High-amperage flow through the winding causes the coil to quickly burn out after just a few hours of continuous operation. To prevent that, continuous duty relays are made from thinner wire with higher resistance. Although they can remain energized for longer periods of time, continuous duty relays are sensitive to voltage drop, leading to relay chatter.

► TECHNICIAN TIP

Continuous and intermittent duty magnetic switches can look identical but will cause problems if not used in the correct application. Continuous duty relays when used to operate glow plug or starter motor solenoids will chatter during cranking. Intermittent duty relays will burn out if left energized for a few hours. Always verify the type of mag switch is meant for its intended applications.

FIGURE 10-39 A. The windings of intermittent duty mag switches are thicker. Thicker windings use more amperage but stay engaged longer when available battery voltage drops during cranking. **B.** Continuous duty relays use thinner, more resistive winding, which will not burn out due to high current flow.

Solenoids

Solenoids are devices with a movable core that converts current flow into mechanical movement (**FIGURE 10-40**).

Solenoids are used with starter motors to engage the drive mechanism while switching heavy current into the motor. They are also used to actuate door lock mechanisms, control air and hydraulic flow, move shut-off levers on fuel systems, and in any other place where electric control of mechanical movement is needed. See **FIGURE 10-41.**

Solenoids can be either pull-in type or push-and-pull type. In pull-type solenoids, an electromagnet pulls a soft iron core into the coil. To prevent a high amount of amperage being drawn by the solenoid and possibly burning out the coil, two coils are used. The first coil is a pull-in winding, which uses thick wire windings developing high magnetic field strength.

FIGURE 10-40 Solenoids may use a spring to return the actuator to a resting position.

FIGURE 10-41 Push-and-pull-type solenoids. Reversing the direction of current flow through the winding changes its polarity. The magnetic actuator will be either pulled or repelled by the magnetic field.

A second hold-in coil “holds” the core in place after the pull-in winding is electrically disconnected. Solenoids of the push–pull type use a permanent magnet instead of an iron core to produce bidirectional movement. By changing the polarity of the coil, the magnetic field around the permanent magnet core can either repel or attract the coil.

► TECHNICIAN TIP

It is important for the pull-in winding of a solenoid to be electrically disconnected after a solenoid is initially engaged. The thinner, more resistive windings of the hold-in winding will take over from the pull-in windings and keep the core engaged. If the solenoid remained engaged, the pull-in windings would burn out due to excessive current flow. Adjustment of solenoid travel is crucial to prevent this from happening by ensuring that the winding is not disconnected internally. Adjustable linkage on the solenoid plunger should be checked against the manufacturer’s specifications (**FIGURE 10-42**).

FIGURE 10-42 This injection pump shut-off solenoid has a high-amperage pull-in and low-amperage hold-in winding to move the control rack from a no-fuel position.

► Wrap-Up

Ready for Review

- A basic electrical circuit includes a power supply, a fuse, a switch, a load, and wires connecting them all together. More complex circuits also include circuit protection devices, a control device, and load and connecting wires.
- According to conventional theory of current flow, the positive power is the supply side of the circuit, and the ground is the return side of the circuit.
- Many machines connect the chassis and body to the negative battery terminal, which means most of the metal components on the machine are grounded.
- A component with no ground connection results in an open circuit and no current flow.
- There are three types of short circuit: short to ground, short to power, and unintended high resistance.
- An open circuit has infinite resistance.
- Unintended high resistance in a circuit causes a reduction in amperage in the circuit as well as a drop in voltage at the resistance.
- Volts, amps, and ohms are three basic units of electrical measurement.
- The higher the resistance, the less amperage that will flow in the circuit for any particular voltage.
- The lower the resistance, the higher the current flow in the circuit.
- Ohm’s law is a mathematical formula that expresses the relationship among volts (V), amps (A), and ohms (R): $A = V \times R$.
- Most of the time, when circuits fail, it is because the current flow is too low or nonexistent.
- Circuits come in two basic configurations—series circuits and parallel circuits. The two types can also be combined into what is called a series-parallel circuit.
- In a series circuit, if there is more than one resistance in the circuit, those resistances are connected one after the other; thus, the resistances add up.
- Excessively high current flow through circuits produces heat that has the potential to overheat conductors or

components to the point where the insulation melts, and a fire can result.

- ▶ Traditional fuses, fuse links, and circuit breakers are connected in series and use heat produced from excessive current flow in overloaded circuits to open the circuits.
- ▶ Protection devices are designed to prevent excessive current from flowing in the circuit.
- ▶ Protection devices such as fuses and fusible links are sacrificial, meaning that if excessive current flows, they will burn out and need replacement.
- ▶ Circuit breakers are resettable. A fuse or circuit breaker should be overrated by about 10–15% to prevent accidental tripping.
- ▶ Virtual fuses save not only the cost of the fuse but also that of the fuse holder and the largest cost associated with using a traditional fuse—the wiring to and from the fuse.
- ▶ A typical relay has a control circuit and a load circuit.
- ▶ Magnetic switches are identical in function to relays except that they switch even larger amounts of current and have atypical dimensions.
- ▶ Solenoids are devices with a movable core that converts current flow into mechanical movement.
- ▶ Solenoids can be either pull-in type or push-and-pull type. In pull-type solenoids, an electromagnet pulls a soft iron core into the coil. Solenoids of the push-pull type use a permanent magnet instead of an iron core to produce bidirectional movement.

Key Terms

circuit breaker A device that trips and opens a circuit, preventing excessive current flow in a circuit. It is resettable to allow for reuse.

combination (series-parallel) circuit A circuit that uses elements both of series and parallel circuits.

e-fuse A software-controlled fuse that uses field effect transistors for the circuit control device. Also called *virtual fuses*.

field effect transistor (FET) A unipolar transistor that uses an electric field to control the conductivity of a semiconductor material.

grounded circuit A circuit characterized by an unwanted low-resistance connection between battery positive power and chassis ground.

intermittent circuit A circuit characterized by uneven current flow.

Kirchhoff's law A law that states that the sum of the current flowing into a junction is the same as the current flowing out of the junction.

parallel circuit A circuit in which all components are connected directly to the voltage supply.

polymeric positive temperature coefficient (PPTC) Device (resettable fuse) A thermistor-like electronic device used to protect against circuit overloads. Also called *resettable fuse*.

resistive circuit A circuit in which grounds and power connections cannot properly function due to overly high resistance.

series circuit The simplest type of electrical circuit, with multiple loads but only one path for current to flow.

short circuit An electrical circuit that is formed between two points, allowing current to flow through an unintended pathway.

thermal fuse A type of fuse opened by heat produced from resistance caused by high-amperage flow.

type 1 circuit breaker A cycling circuit breaker that automatically resets.

type 2 circuit breaker A noncycling circuit breaker.

type 3 circuit breaker A circuit breaker that requires manual reset.

virtual fuse A software-controlled fuse that uses field effect transistors for the circuit control device. A circuit protection strategy that monitors circuit amperage with software and shuts off the circuit when amperage exceeds a predetermined threshold. Also called *e-fuses*.

watt's law A law that defines the relationship between power, amperage, and voltage.

Review Questions

1. Which of the following are basic parts of an electrical circuit?
 - a. Power source
 - b. Conductors
 - c. Loads
 - d. All of the choices are correct.
2. Which of the following statements is/are correct concerning the term “operational state”?
 - a. Open and closed are the terms used to describe whether current is flowing through a circuit.
 - b. An open circuit's electrical pathway is broken or unconnected.
 - c. An open circuit means current cannot flow because there is an open gap between two ends of the circuit.
 - d. All of the choices are correct.
3. Which of the following is *not* correct concerning parallel circuits?
 - a. There are two or more pathways for the current.
 - b. The voltage applied to each branch is the same throughout the circuit.
 - c. If one branch of the circuit is broken, current will continue to flow in the other branches.
 - d. Total circuit resistance is always more than the resistance of the smallest resistor.
4. Which of the following is/are correct concerning combination circuits?
 - a. Combination circuits use elements in both parallel and series circuits.
 - b. Combination circuits are the most common types used in mobile off-road equipment.
 - c. Typically, the power and control circuits are in series, but the loads are in parallel.
 - d. All of the choices are correct.

5. Which of the following is *not* correct concerning Ohm's law?
 - a. Ohm's law is often used by a technician.
 - b. An understanding of Ohm's law can help you better understand how electricity behaves.
 - c. Ohm's law defines the relationship between current, resistance, and voltage.
 - d. Simply stated, Ohm's law requires 1 volt to push 1 amp of current through a circuit that has a resistance of 1 ohm.
 6. Why do machines often use a 24-volt system?
 - a. Reducing amperage not only reduces resistance but also the size of conductors.
 - b. Voltage drops in the system are reduced.
 - c. Both A and B
 - d. Neither A nor B
 7. Which of the following are common points for resistances to develop?
 - a. Battery terminals
 - b. Lightbulb sockets
 - c. Connector sockets
 - d. All of the choices are correct.
 8. Which of the following is *not* a type of thermal fuse?
 - a. Cartridge type
 - b. Modular type
 - c. Blade type
 - d. In-line type
 9. Which type of circuit breaker must be reset by depressing a reset button?
 - a. Type 1
 - b. Type 2
 - c. Type 3
 - d. Type 4
 10. Which of the following is/are correct concerning inspecting and testing circuit protection devices?
 - a. Protection devices such as fuses and fusible links are sacrificial, meaning that if excessive current flows, they will blow or trip and have to be replaced.
 - b. Circuit breakers can be reset.
 - c. Fuses, fusible links, and circuit breakers are available in various ratings, types and sizes, and must always be replaced with the same rating and type.
 - d. All of the choices are correct.
- not proportionately lower amperage to the amount of resistance. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says circuits found in mobile off-road equipment are classified in an operational state of open or closed. Technician B says circuits found in mobile off-road equipment are classified in the failure mode of blocked as well as shorted or open. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 4. Technician A says a series circuit is a circuit with multiple loads and only one path for current to flow. Technician B says in a series circuit total circuit resistance is equal to the sum of the individual resistances. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 5. Technician A says Watt's law, which is related to Ohm's law, explains the relationship between resistance and amperage. Technician B says increasing amperage through a circuit produces proportionally more resistance. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 6. Technician A says a grounded circuit should not be confused with a "dead short," which is a different condition. Technician B says a common example of a grounded circuit would be a battery or power cable insulation rubbing against the negative ground chassis frame. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 7. Technician A says when circuits are overloaded with current hungry components, or grounded circuits, it is the quickest way to cause damage to wiring, or even start fires. Technician B says a 20-amp fuse will open at 32–33 amps of current. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 8. Technician A says fuse links are short sections of wire installed in series with larger diameter conductors. Technician B says when the gauge on the main conductor is at halfway, the fuse link will overheat and melt as excessive amperage passes through the wire. Who is correct?
 - a. Technician A
 - b. Technician B

ASE Technician A/Technician B Style Questions

1. Technician A says circuits are pathways made by electrical conductors that enable the flow of electrons. Technician B says a variety of classifications are used to describe circuit configurations and failures. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says resistance is electrical friction. Technician B says resistance will lower voltage but in a circuit will

- c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B
- 9.** Technician A says a polymeric positive temperature coefficient (PPTC) device is a thermistor-like electronic device used to protect against circuit overloads. Technician B says PPTCs are commonly known as manual resettable fuses. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B
- 10.** Technician A says virtual fuses, or e-fuses, are a recent innovation in circuit protection. Technician B says virtual fuses are software-controlled fuses that use field effect transistors (FETs) as the circuit control device. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B

CHAPTER II

Electrical Test Instruments

Knowledge Objectives

After reading this chapter, you will be able to:

- **KI 1001** Classify and identify the applications of electrical test instruments used in off-road mobile equipment service.
- **KI 1002** Describe the setup of a digital multimeter (DMM) and procedures for performing basic electrical measurements.
- **KI 1003** Describe the function and setup of a circuit tracer when performing basic electrical troubleshooting.
- **KI 1004** Describe the function and setup of graphing meters and oscilloscopes when performing basic electrical troubleshooting.
- **KI 1005** Describe the function and setup of electronic service tools when performing basic electrical troubleshooting.

Skills Objectives

After reading this chapter, you will be able to:

- **SI 1001** Check meter shunts.
- **SI 1002** Test electrical/electronic circuits and components using appropriate test equipment.

► Introduction

Diagnosing and repairing electrical problems requires not only logic and deductive reasoning but electrical test tools too. A variety of electrical test instruments are needed, ranging from the simple test lights and electrical multimeters to more elaborate instrumentation for checking fault codes and viewing electrical signal wave forms.

► Electrical Test Instruments

K11001, S11001

Self-Powered Test Light

Self-powered **test lights** are like regular test lights except that they contain a 1.5-volt battery (FIGURE 11-1).

FIGURE 11-1 A self-powered electrical probe.

FIGURE 11-2 A self-powered test light can be used to find open, shorted, and grounded circuits after disconnecting the circuit from machine power and ground. The battery will supply the ground connection through the alligator clip.

Self-powered lights can be used to check for both open circuits and grounded circuits when either chassis power or ground is removed from the circuit (FIGURE 11-2).

The internal battery can supply current needed to illuminate the light. To check for an opening in a circuit, the machine battery is first disconnected. The light's alligator clip is connected to ground, and the circuit is probed sequentially from the switch or power supply to the load. Where the test light glows, the circuit is closed from machine ground to power. An open circuit prevents current from traveling from the ground to an insulated positive. For example, a broken wire between a heater blower motor and fuse will illuminate between the blower motor and break in the wire, but not after the break and before the fuse.

Grounded circuits are checked in a similar manner. While probing the circuit, its switches and connectors are opened. The light will stay illuminated in the section that is grounded. However, the light will go out after the section of circuit with an unintentional ground is disconnected. Self-powered volt-meters with probes are also useful for close-quarter probing of electrical circuits.

► TECHNICIAN TIP

A 12- or 24-volt battery current will easily blow the bulb out of self-powered test lights, so battery current should always be removed when

You Are the Mobile Heavy-Duty Technician

In the equipment fleet that you help maintain, quite a high number of wheel loaders are developing electrical short circuits, grounded circuits, and open circuits in the wiring connecting the operator's console to the rear lights. Many of the problems are likely the result of wiring being improperly secured, insulated, and tied at the factory. Repairing the wiring problem has become very time consuming, as several wiring circuits pass through the cab of the machine. Often, the panels must be removed to replace or repair the wiring. Even after replacing large sections of wiring between the body panels, many of these same wheel loaders require further repairs. Later repairs have to be made to the wiring that connects the signal and brake lights, as corrosion has taken place due to punctures from test lights. While reviewing maintenance strategies and procedures, consider the following:

1. What electrical test instrument would you recommend using to find shorts, grounded circuits, and open circuits behind the wheel loaders' body panels?
2. What electrical test instrument would you recommend for finding grounded circuits in the wiring between the lights and the grounded wire that is routed through the cab?
3. What maintenance recommendations would you make to prevent further repeat repairs of wiring after technicians have performed initial repairs?

using these lights. Although 1.5 volts is relatively low, it is still enough to damage computer circuits. Self-powered test lights should never be used in electronic circuits using semiconductors—that includes sensors.

SAFETY TIP

High voltage from electric drives, the latest common rail injectors, and other electric systems can easily kill or cause serious physical harm if pierced by a technician. Always ensure appropriate power disconnect switches are removed when working around these circuits. Also, never pierce wiring covered in heavy protective loom or brightly colored insulation without first determining what voltage the conductors are carrying. The bright color and insulation often designate high voltage or sensitive circuits (**FIGURE 11-3**).

FIGURE 11-3 High-voltage cables such as those on electric-drive equipment have heavy protective insulation, which is brightly colored.

Self-Powered LED Test Lights

One of the disadvantages of incandescent test lights is that they can draw excessive current from a circuit to operate the bulb. In some cases, the additional load may damage a circuit. Using light-emitting diodes (LEDs) instead of an incandescent bulb overcomes this difficulty and adds capabilities to a test light. A popular type of LED test light is battery powered and has two LEDs—one red and the other green. With two LEDs, the technician can find out what the polarity of a circuit is as it's being tested. For example, if the light's alligator clip is connected to ground and the probe is connected to a positive polarity, the red LED comes on. A green light indicates it's a ground or connected to negative polarity. One disadvantage of LED lights is that they provide no indication of a circuit voltage and will be relatively bright between 1.5 and 3 volts. An incandescent light changes brightness depending on the circuit's voltage.

Multimeters

Multimeters are electrical measuring instruments combining functions of at least voltage, resistance, and amperage measurement into a single compact instrument. Digital multimeters are the most common category of multimeters and provide numerical displays of electrical data (**FIGURE 11-4**).

Analog meters use a sweeping needle that continuously measures electrical values (**FIGURE 11-5**).

Digital multimeters are almost exclusively used today because they are easiest to use and draw the least amount of current from circuits being measured. Sampling very little of a circuit's own current to take a measurement is a characteristic of **high-impedance multimeters**. High impedance refers to a meter's internal resistance to current flowing from a live circuit into the meter when measuring voltage and amperage. In sensitive electronic circuits, a test light or analog meter can act like a load and use too much current. The result is an overloaded or damaged circuit.

FIGURE 11-4 A digital multimeter with typical basic features.

FIGURE 11-5 An analog meter uses a needle and sweeping scale to measure properties of electrical current.

Basic Multimeter Electrical Measurements

Before using a multimeter, it is important to understand the basic measurements that it can produce. A multimeter measures resistance, continuity, voltage, and amperage:

- 1. Resistance**—Measures circuit resistance in Ohms to determine whether it is within specifications. Wire coils and heating elements are examples of common devices where a measure of resistance determines serviceability. Open and short circuits are easily detected using the ohmmeter to measure resistance (**FIGURE 11-6**).
- 2. Continuity**—Determines whether two points are electrically connected. Continuity is also valuable when checking for opens and shorts.
- 3. Voltage**—Measurements are used to determine whether a component or circuit has the correct amount of available voltage. Measuring voltage drops in a circuit can help evaluate excessive resistance in high-amperage circuits such as the starting circuit. A voltmeter behaves like a pressure differential gauge by measuring the difference in electron pressure between two points in a circuit.

FIGURE 11-6 Features of a basic DVOM.

- 4. Amperage**—Most measurements of amperage are performed at levels higher than multimeters can typically handle, so an inductance amp clamp is used instead. However, meters are usually capable of measuring up to 10 amps of current flow. Starter draw and alternator output are two common measurements of amperage regularly made using multimeters with an inductance clamp meter accessory.

Multimeters may also perform additional electrical measurements including the following:

- Diode testing
- Frequency
- Capacitance
- Temperature
- Duty cycle
- Transistor testing
- Continuity tester with beeper
- Waveform display
- Engine RPM

Manual and Auto-Ranging Meters

Multimeters are available as auto- or manual-ranging types. An **auto-ranging multimeter** has fewer positions on its range selection knob. When set to amps, volts, or ohms, the meter automatically selects the correct range when meter test leads are connected to a circuit.

This feature contrasts with **manual-ranging multimeters** that must first be set to the correct range based on anticipated values measured. For example, the DC volts range of a manual meter may include a setting of 200 mV, 2 V, 20 V, 200 V, and 500 V. To measure 12-volt battery voltage, the range value just above the anticipated voltage is the 20-volt scale (**FIGURE 11-7**).

An auto-ranging meter would only require selecting DC volts, and the meter would do the rest. Auto-ranging meters can be slower to measure electrical values because they need time to adjust the operating range. As an alternative, auto-ranging meters can usually be set to operate as manual-ranging units.

With either automatic or manual-ranging meters, it is important to learn the electrical symbols and units of measurement listed in **TABLE 11-1**.

FIGURE 11-7 A manual-ranging meter will move the decimal point for many electrical measurements.

TABLE 11-1 Symbols and Meanings for Electrical Units of Measurement

Symbol	Meaning
M	Mega or million
K	Kilo or thousand
m	Milli or one thousandth
μ	Micro or one-millionth
$\bar{V}$	V dc
$\tilde{V}$	V ac
mV	Millivolts (0.001 V or 1/1,000 V)
A	Amperage (amps)
mA	Milliamps (0.001 A or 1/1,000 A)
μ A	Microamps (0.000001 A or 1/1,000,000 A)
Ω	Resistance (ohms)
k Ω	Kilo-ohms (1,000 ohms)
M Ω	Megohms (1,000,000 ohms)
$\Rightarrow$	Continuity beeper
Diode $\rightarrow $	Diode testing
Hz	Frequency (hertz, which is cycles/sec)
dB	Sound (decibels)
F	Capacitance (farad)
μ F	Microfarads
nF	Nanofarads
Touch Hold & Auto HOLD	The last recorded stable reading
MIN MAX	Highest, lowest recorded readings
OL	Out of range

TECHNICIAN TIP

When making measurements, and performing diagnostic tests with auto-ranging meters, the display may change continuously for some time until the correct range is established. If the measured value changes or test lead probes move too much, the meter may begin to auto-range once again. The process can lead to incorrect results if measurements are taken too quickly. Using the peak and hold feature or auto-hold will help to produce more accurate values. Otherwise, more patience and care is required when using these meters.

Meter Shunts

Before using a digital meter, one of the first things to check is whether its shunts or fuses are in place and functioning. Shunts are internal conductors with a small calibrated resistance, which directs some current flow into the meter when measuring amperage (**FIGURE 11-8**).

Almost all circuit current will pass through meter shunt, but some resistance is needed to send current into the measuring circuits of the meter. Shunts operate like fuses and have a maximum rating. A shunt should blow in an extremely short

FIGURE 11-8 An ammeter shunt allows most of the current to pass through the shunt while allowing some small amount of current into the meter's measurement mechanism.

FIGURE 11-9 Checking the ammeter shunts should show continuity between the volts/ohm/amp red and amperage lead ports.

time if current exceeds the meter's capacity. If an ordinary fuse is used to replace a fast-blowing shunt, current will enter and damage the meter in the time it takes to open the ordinary fuse.

Shunts are checked by inserting the positive lead probe, while in the volt/ohm port, into the amperage probe port (**FIGURE 11-9**).

A meter set to check continuity or resistance should display continuity and some resistance. If two amperage ports are used on a meter, the larger amperage shunt will have a higher resistance than the low-amperage shunt. To check meter shunts, follow the steps in **SKILL DRILL 11-1**.

► Electrical Measurement with Multimeters

K11002, S11002

Multimeters are versatile instruments that allow the technician to take a variety of measurements. Three types of

SKILL DRILL 11-1 Checking Meter Shunts

1. Plug test lead in volts/ohms input.
2. Select ohms' range.
3. Insert probe tip into mA input and read value. A small amount of resistance should be noted when probing the amperage inputs with the positive volt/ohm probe.
4. Insert probe tip into Amp input and read value. It should have a larger amount of resistance than the mA input.

FIGURE 11-10 Ohmmeters use a small amount of current supplied by a battery to measure resistance. Voltage through the circuit is actually measured by the meter, which is reported in ohms. Voltage is proportional to circuit resistance.

measurements—voltage, resistance, and amperage—can be taken from circuits in three different ways. Understanding them is necessary to prevent meter damage and ensure accurate measurements.

Measuring Resistance—Ohmmeters

Measuring resistance is one of the most common functions of a multimeter, and many electrical diagnoses are made using an ohmmeter. By checking the resistance or circuit continuity with an ohmmeter, a circuit can be evaluated for shorts, opens, or high resistance. An ohmmeter uses a small amount of electrical current from an internal battery and sends it through a circuit or component.

The amount of current that flows through the component or circuit will depend on the circuit's resistance (**FIGURE 11-10**).

If the return current is high, the circuit resistance is low, and if the return current is low, the circuit resistance is high. Ranging the meter is done by using resistors to change the amount of current entering the circuit. This means that when selecting a meter range of higher resistance—for instance,

100 mega ohms rather than a 10-ohm scale—more current must leave the meter to pass through the highly resistive circuit (**FIGURE 11-11**).

FIGURE 11-11 Manual or auto-ranging meters extend the range of the ohmmeter by substituting different resistances in series with the internal power source.

Because ohmmeters are self-powered, it is critically important to remember that ohmmeters should never be connected to a powered circuit. Connecting an ohmmeter into a powered circuit will blow the fuse or battery in the meter or otherwise damage the meter. Semiconductor circuits and sensors should not be checked with an ohmmeter, as the meter current may damage the device (FIGURE 11-12).

Ohmmeters are ineffective when checking for resistances in high-amperage, low-resistance circuits, such as when measuring battery cable voltage loss. Measuring voltage drop with a voltmeter when a circuit is operating is a more effective way of measuring resistances (FIGURE 11-13).

When measuring with an ohmmeter, it is important to observe how a meter displays infinite resistance or an open

circuit. Some meters will display either a 1 or 0 to indicate an open circuit (FIGURE 11-14).

It is important to understand also the range that the display is reporting. Million, thousand, and hundred are common ranges for an ohmmeter, and the displayed value may need to be multiplied by multimeter range.

When using an ohmmeter:

- The circuit must never be powered.
- The meter is connected in parallel across the circuit or component to measure the voltage dropped by the circuit resistance.
- It is not necessary to observe polarity when connecting test leads.

FIGURE 11-12 Because ohmmeters indirectly measure voltage, it is critical to remove power from a circuit before connecting the meter. Meter damage will occur otherwise.

FIGURE 11-13 A voltmeter is best used to check for resistance in high-amperage circuits. Excessive voltage drop means the circuit has excessive resistance.

FIGURE 11-14 The ohmmeter display value may have to be multiplied to obtain the correct resistance value. On a 10k scale the number “1” would indicate a value multiplied by 10,000, meaning the actual value is 10,000 ohms.

- The positive test lead is connected to the ohms port and the negative lead to the common port of the meter.
- The meter needs to be properly ranged if not using an auto-ranging meter. Start at the highest range values and work down if the resistance is unknown.
- Not to be used with semiconductors and potentially inaccurate when testing diodes.

Measuring Voltage—Voltmeters

Voltmeters measure the difference in electrical pressure between two different points in the circuit (**FIGURE 11-15**).

Using a voltmeter is similar to measuring a pressure drop between two points. When measuring volts, the meter should be connected in parallel with the voltage source (**FIGURE 11-16**).

FIGURE 11-15 Only a small amount of current actually enters the voltmeter. Voltmeters with high internal resistance are called high-impedance meters.

FIGURE 11-16 Voltmeters are connected in parallel in a circuit.

On mobile off-road equipment, you would commonly measure voltage drops across loads, determining whether there is sufficient voltage to a component, or measure sensor supply voltages. In any of these cases, the meter would be set to its 20 volts for 12-volt systems or 40 volts for 24-volt systems. Auto-ranging meters are set to the DC volts scale.

The positive meter lead probe is inserted into the volt-ohms port and the negative to the common port (**FIGURE 11-17**).

If the circuit polarity is not correctly observed (i.e., the negative probe is connected to the positive side of the circuit and vice versa), digital meters will show a negative volts symbol.

Best practices to use when measuring voltage include:

- Connecting the voltmeter in parallel with the circuit
- Observing polarity when measuring DC volts but not AC voltage (**FIGURE 11-18**)
- Ranging AC and DC volts separately
- When not using an auto-range meter, selecting the first voltage scale that is higher than the anticipated voltage; if unknown, starting at the highest scale
- Connecting the positive lead to volts/ohms port and the negative lead to common port
- Ensuring that the circuit is powered.

FIGURE 11-17 When connecting a voltmeter, the polarity of the meter and circuit should match. A polarity indicator uses electron theory and will show a meter is connected incorrectly to a circuit.

When measuring DC volts, the meter must be connected to the circuit with the correct polarity or the meter reading will be incorrect.

When measuring AC volts, the polarity of the meter to the circuit is unimportant and will not affect the meter reading.

FIGURE 11-18 Polarity does not need to be observed when measuring AC voltage.

TABLE 11-2 Multimeter Features to Protect Meter and User

Risk	Protection
Electrical arcing from transients high voltage sources (lightning, load switching)	Independent certification to meet CAT III-1000 V and CAT IV-600 V or higher
Voltage damage to meter while in continuity or resistance ranges	Overload protection in ohms up to the meter's volt rating.
Measuring voltage with test leads in amperage inputs	Fast blowing, high energy fuses rated to the meter's voltage rating. Use induction clamps to measure amperage
Shock from accidental contact with live components	Double insulated test leads, recessed and/or shrouded with finger guards

Voltmeters commonly include several protections against damage and safety risks (TABLE 11-2).

SAFETY TIP

Multimeters can and do blow up, causing personal injury and equipment damage. Safety features—such as using PTC thermistors in the ohmmeter, which become highly resistive when heated—are built into meters to limit damage to the meter. Voltage circuits are capacitive coupled, eliminating a direct connection to meter circuits. Low-impedance ammeters use **shunts** that blow when overloaded. Double insulation of meters, shrouded connectors, and the use of finger guards are other safety features. Check meters before using to see that insulation is not melted, cut, or cracked. Connectors and leads should not show any damage, such as insulation pulled away from end connectors. Probe tips should not be loose or broken off. Make sure the meter is safe for the application in which it is being used. IEC 61010 is a safety standard that establishes safety limits for meters. A Cat I meter in this standard, which is satisfactory for most technicians, should not be used to check voltages above 600 volts continuous, or 2,500 volts at peak. The top-rated CAT III meter can operate with 1,000 volts continuous and 8,000 volts transient peak (FIGURE 11-19).

FIGURE 11-19 This meter has a safety rating of CAT III at 600 volts and CAT IV at 1,000 volts.

Measuring Amperage—Ammeters

Ammeters measure the quantity of electrons flowing through a circuit per second of time. Amperage is the volume aspect of current flow, and voltage is the pressure of electrical flow. Measuring amperage requires that the circuit be broken and the meter placed in series with the circuit so that all the current flows through the meter shunts. See FIGURE 11-20 and FIGURE 11-21.

Because all circuit current flows through the meter, the meter should never be connected to a current source in parallel, as it is the equivalent of shorting out a circuit. Two ports for the positive leads are commonly used to measure low amperage—milliamps, and amperage above 1 amp. Failure to move meter leads from low- to high-amperage ports will blow the meter shunt and may even damage the meter.

FIGURE 11-20 Ammeters use shunts that allow most circuit current to pass through the shunt rather than the meter.

Best practices to use when measuring amperage include:

- Ensuring that the circuit is powered.
- Ensuring that the ammeter is connected in series, causing all the current in the circuit to flow through the meter shunts.
- Observing polarity when measuring DC amperage (**FIGURE 11-22**).
- Choosing the correct shunt or port in the meter for connecting leads based on anticipated amperage. The common port is used for the negative lead, and A, mA and uA are used for the positive lead (**FIGURE 11-23**).
- When not using an auto-range meter, selecting the first amperage scale that is higher than the anticipated amperage; if unknown, start at the highest scale.
- When measuring more than 10 amps of current, use an inductive-type probe or dedicated amp clamp.

FIGURE 11-21 Connecting an ammeter in series to measure amperage.

FIGURE 11-22 Ammeters require connection using correct polarity as noted using this analog ammeter. Digital meters will indicate the polarity is incorrect.

FIGURE 11-23 Connecting an ammeter in series to measure parasitic current draw that can drain a battery.

Inductive Amp Clamps

In powered circuits, **inductive amp clamps** placed around a conductor are used to measure amperage. These devices work by measuring a conductor’s magnetic field strength, which is proportional to amperage (**FIGURE 11-24**).

While using an amp clamp, an electrical circuit does not need to be disturbed by connecting a meter in series.

Two types of amp or inductive clamps are used, which are connected to the voltage/common ports of a multimeter.

- Measuring AC only
- Measuring both DC and AC (**TABLE 11-3**)

Clamps that measure AC current use a current transformer built into the pickup. The alternating current passing through a conductor produces a magnetic field, which induces voltage

FIGURE 11-24 An inductive amp clamp measures the strength of the magnetic field around a conductor using a Hall-effect sensor. Magnetic field strength is proportional to amperage.

TABLE 11-3 Differences Between Features of an AC and an AC/DC Self-Contained Induction Clamp

	AC	AC/DC
Feature		
Output current	Current	Voltage
Scale factor	1 milliAmp per Amp	1 milliVolt per Amp
Sensor	Current transfer	Hall effect
Battery	No	Yes

through mutual induction into transformer windings. Using a specific turn ratio in the transformer, such as 1,000:1, voltage induced inside the transformer is calculated as a value for amperage. These clamps typically generate 1 millivolt per measured amp, which can be measured by the multimeter. DC clamps use Hall-effect technology. Hall-effect material found in these sensors changes their electrical resistance based on the strength of a magnetic field.

Measuring Temperature

Multimeters use a thermocouple accessory to measure temperature by contact. Heating the thermocouple produces voltage proportional to temperature. **Type K thermocouples** are low-cost, general-purpose, temperature-sensing elements and are connected to the same meter terminals for measuring DC millivolts. Internal meter circuits convert the voltage measurements into a temperature reading.

Diode Scale

The low-voltage settings of an ohmmeter may not properly evaluate a diode, as a good silicon diode requires approximately 0.5–0.7 volt to forward bias or conduct current. Below this voltage, the diode may appear to block current in both directions. When placed in the diode range, a meter will put out higher voltage than the barrier voltage of 0.7 volt, to cause the diode to reverse and forward bias.

► Circuit Tracers

Circuit tracers, also called **wire tracers**, are electronic service tools used to trace a single wire over a distance where multiple wires are bundled, shorted, or open. Telephone companies once commonly used these to help field technicians locate problematic phone circuits. These units can identify wires deeply buried behind walls or in tightly bundled harness.

Several methods are used to identify circuit problems. Commonly though, one part of the signal tracing unit is clipped to a suspect wire and ground. When switched on, the unit injects a strong, two-tone square wave radio signal into the wire. The receivers consist of a sensitive radio with an audio amplifier and speaker. Slowly waving this device over a group of wires will detect where a conductor is located and where it ends. See **FIGURE 11-25** and **FIGURE 11-26**.

FIGURE 11-25 Using the circuit tracers after connecting the signal generator to a defective circuit.

FIGURE 11-27 A graph of a pulse-width-modulated signal waveform obtained using a graphing meter.

FIGURE 11-26 The transmitter and receiver of a circuit tracer used to trace electrical wires for open and short circuits.

The intensity of the sound produced by the signal or the flickering of an LED light varies with proximity to the wire. The probe's tip is insulated for safety purposes.

► Graphing Meters and Oscilloscopes

K11004

One of the latest diagnostic tools is a digital **graphing meter** used to analyze electrical waveforms produced by sensors, motors, actuators, and alternators. These test instruments plot an electrical value of a signal over time, displaying an easy-to-read graph with time on the x -axis and the signal value on the y -axis (**FIGURE 11-27**).

FIGURE 11-28 A graphical display of the electrical signal supplied to an injector using a Picoscope. Two channels measure voltage – blue trace, and amperage – red trace.

Component serviceability can be determined by analyzing the waveform or comparing it to known signals of good quality (**FIGURE 11-28**).

Component serviceability can be determined by analyzing the waveform or by comparing it to known signals of good quality. For example, a Hall-effect sensor may have intermittent problems that may not be detected by the machine's onboard diagnostic system. A faster-sampling graphing meter is better suited to detect a problem like this.

The life expectancy of an electric motor is another example of a component that can be evaluated by examining the small changes in current and voltage spikes caused by worn brushes. Scanners and OEM diagnostic software can also graph values captured by the ECM associated with a machine system, such as engine, transmission, hydraulic system, or body control, through the diagnostic connector. Dedicated graphing meters connect directly to a sensor, circuit, or component that requires testing. Whereas a single-channel graphing meter has only one input,

two-, three-, and four-channel units have as many inputs and can graph the values together or on separate screens for comparative purposes. Oscilloscopes have more elaborate display modes to capture one-off signal glitches or jitter. Selectable signal triggers, sources, display rulers, slope measurement, and a wider variety of display options are also available with oscilloscopes.

When performing electrical circuit diagnostics, purpose-made jumper wires, fused jumper wires, and breakout boxes are helpful for quickly and effectively diagnosing problems without damaging wiring or connectors by back-probing or piercing wires (**FIGURE 11-29**).

A breakout box is connected in series with a major component or wiring harness to an ECM. Signals on each wire in the harness will correspond to a pin on the breakout box (**FIGURE 11-30**).

FIGURE 11-29 Terminal test kit for specific terminal types that will not damage wires or connectors while testing.

FIGURE 11-30 A breakout box with two matched connectors, female and male, connect in series to major wiring harnesses to perform pin-point diagnostic tests.

OEM templates, which are thin plastic sheets with printed numbers or letters, can be obtained to lay over the pins, helping to identify specific pin functions or circuit numbers. Smaller breakout harnesses, which connect to sensors or special wiring harnesses, are also useful to make pinpoint tests of circuits required by diagnostic procedures (**FIGURE 11-31**).

► Electronic Service Tools

K11005

A variety of OEM diagnostic software types are available and are used to read serial data from a machine data link connector. Most OEM diagnostic software is designed to run on a personal computer (PC) under Microsoft® Windows™ and, along with a data link adapter, the software can translate the serial data into a format that can be read by the technician. More sophisticated OEM diagnostic software uses bidirectional communication between the PC, communication adapter, and the machines ECM to send commands that can actuate output devices or cause the ECM to enter diagnostic routines such as performing cylinder cutout tests, solenoid function tests, and more.

SAE Requirements for Onboard Diagnostics

The SAE has developed onboard diagnostic (OBD) standards that most OEM diagnostic software use. These standards include the following:

1. Standards for 6- and 9-pin DLC connectors
2. J1978—describes the basic functions that an OBD scanner must support, including these:
 - Automatic hands-off determination of the communication protocol

FIGURE 11-31 Purpose made jumper wires with terminal ends matching specific types of connector terminals are used to perform pin-point tests of voltage, amperage, and resistance.

- Obtaining and displaying the status of OBD evaluations such as supported and completed readiness or monitor tests and lamp MIL lamp status
 - Obtaining and displaying diagnostic trouble codes (DTCs)
 - Obtaining and displaying emissions-related data from engine parameters
 - Obtaining and displaying emissions-related freeze frame data
 - Clearing stored emissions-related DTCs, freeze frame data, and diagnostic test results.
3. J1979-02—describes diagnostic test modes for emission-related diagnostic data that can be displayed, including the following:
- Request for current powertrain diagnostic data including engine parameters, MIL status, and readiness codes
 - Request for powertrain freeze frame data
 - Request emission-related powertrain DTCs
 - Clear/reset emission-related diagnostic information including MIL status, DTCs, freeze frame, and readiness codes
 - Request exhaust gas sensor monitor test results
 - Request latest onboard monitoring test results for noncontinuous monitor systems (i.e., after treatment catalysts, exhaust gas recirculation [EGR], misfire, etc.).
 - Request latest onboard monitoring test results for continuous monitor systems (i.e., comprehensive component monitor)
 - Can be used to request control of an onboard system and is manufacturer defined
 - This optional mode used to report machine information such as the serial number and possibly calibration information stored in the machine ECM
 - A display screen listing fault codes.

Additional OEM Diagnostic Software Functions

OEM diagnostic software can perform a variety of additional functions:

- *Bidirectional control*—can control selected equipment components or initiate systems actuator or diagnostic tests on command.
- *Graphical display*—can display real-time engine parameters or recorded data in a graphing format.
- *Help menu/trouble code library*—can guide a technician through certain procedures or has a built-in library of all the trouble codes.

- *Printer/Computer output*—connect to a printer or computer and prints or displays information from the machine.
- *Record/playback or snapshot mode*—can record a block of real-time machine system data and replay that information to assist in finding the root cause of a malfunction.
- *Reprogramming of machine ECM*—can perform off-board or onboard reprogramming of a machine's computer modules, specially the powertrain (ECM).
- *Scopes and meters*—can operate as a multimeter (measuring voltage, resistance, amperage, etc.).

Data Link Adapters

Data link adapters are used to translate serial data from the DLC into a format readable by a desktop or laptop computer. The adapter may connect to the PC using a cable connected to a serial port, USB port, or wirelessly over the Internet or Bluetooth communication (**FIGURE 11-32**).

FIGURE 11-32 This data link adapter connected to the machine data link can translate DLC serial data into serial data readable by PCs or laptops. The adapter can communicate using a cable or with another adapter wirelessly over the same radio frequency as wireless Internet, or by using Bluetooth radio frequencies.

► Wrap-Up

Ready for Review

- ▶ A variety of electrical test instruments are needed to diagnose and repair electrical problems.
- ▶ The simplest piece of electrical test equipment used to determine the presence or absence of current is a test light.
- ▶ Self-powered test lights are like regular test lights except that they contain a 1.5-volt battery.
- ▶ Multimeters are electrical measuring instruments combining functions of at least voltage, resistance, and amperage measurement into a single compact instrument.
- ▶ Multimeters can be analog, digital, or high impedance and come in auto-ranging and manual-ranging types.
- ▶ Before using a digital meter, one of the first things to check is whether its shunts or fuses are in place and functioning. Shunts are internal conductors with a small calibrated resistance, which directs some current flow into the meter when measuring amperage.
- ▶ By checking the resistance or circuit continuity with an ohmmeter, a circuit can be evaluated for shorts, opens, or high resistance.
- ▶ Ohmmeters are ineffective when checking for resistances in high-amperage, low-resistance circuits, such as when measuring battery cable voltage loss.
- ▶ Voltmeters measure the difference in electrical pressure or electron velocity between two different points in the circuit.
- ▶ Measuring amperage requires that the powered circuit be opened and the meter placed in series with the circuit so that all the current flows through the meter shunts.
- ▶ Inductive amp clamps are useful tools for measuring amperage without disturbing the circuit.
- ▶ Multimeters use a thermocouple accessory to measure temperature by contact. Heating the thermocouple produces voltage proportional to temperature.
- ▶ Circuit tracers are useful for identifying circuit problems in wires deeply buried behind walls or in tightly bundled harness.
- ▶ Graphing meters allow technicians to assess component serviceability by analyzing the waveforms.
- ▶ When performing electrical circuit diagnostics, purpose-made jumper wires, fused jumper wires, and breakout boxes are helpful for quickly and effectively diagnosing problems without damaging wiring or connectors by back-probing or piercing wires.
- ▶ A variety of OEM diagnostic software types are used to read serial data from a machine data link connector.

Key Terms

analog meter A meter that uses a sweeping needle that continuously measures electrical values.

auto-ranging multimeter A multimeter that has fewer positions on its range selection knob and will automatically select the correct range when meter test leads are connected to a circuit.

circuit (wire) tracer An electronic service tool used to trace a single wire over a distance where multiple wires are bundled, shorted, or open.

data link adapter A device used to translate serial data from the DLC into a format readable by a desktop or laptop computer.

graphing meter An electrical test instrument used to analyze waveforms and graphically plot an electrical value of a signal over time.

high-impedance multimeter A meter that samples very little of a circuit's own current to take a measurement.

inductive amp clamp A device that measures amperage by measuring a conductor's magnetic field strength, which is proportional to amperage.

manual-ranging multimeter A multimeter that must first be set to the correct range based on anticipated values measured.

shunts Internal conductors with small calibrated resistance and that direct current flow into the meter while measuring amperage.

test light The simplest piece of electrical test equipment, which consists of either a 12- or 24-volt incandescent lightbulb connected to an insulated lead and a sharpened metal probe.

type K thermocouple A low-cost, general-purpose, temperature-sensing element connected to the same meter terminals for measuring DC millivolts.

Review Questions

1. Which of the following statements about self-powered test lights is correct?
 - a. Self-powered test lights are like regular test lights except that they contain a 1.5-volt battery.
 - b. Self-powered lights can be used to check for both open circuits and grounded circuits when either chassis power or ground is removed from the circuit.
 - c. The internal battery can supply current needed to illuminate the light.
 - d. All of the choices are correct.
2. What is the usual capability of a multimeter to measure current flow in amps?
 - a. 5 amps
 - b. 10 amps
 - c. 15 amps
 - d. 20 amps
3. Which of the following is *not* correct concerning electrical measurement with multimeters?
 - a. Three types of measurements—voltage, resistance, and amperage—can be taken from circuits in three different ways.
 - b. An ohmmeter uses a small amount of electrical current from an internal battery and sends it through a circuit or component.

- c. The circuit must never be powered when connected to an ohmmeter.
 - d. When using an ohmmeter, it is necessary to observe polarity when connecting test leads.
4. When using a manual-ranging multimeter, what range setting should be selected to measure 12 volts?
- a. 12 volt
 - b. 18 volt
 - c. 20 volt
 - d. 24 volt
5. Which of the following statements about inductive amp clamps is correct?
- a. In powered circuits, inductive amp clamps placed around a conductor are used to measure amperage.
 - b. These devices work by measuring a conductor's magnetic field strength, which is proportional to amperage.
 - c. Both A and B
 - d. Neither A nor B
6. Type K thermocouples are a(n) _____ temperature-sensing element.
- a. high-cost
 - b. inefficient
 - c. general-purpose
 - d. rudimentary
7. Which of the following statements about the diode scale is correct?
- a. The low-voltage settings of an ohmmeter may not properly evaluate a diode, as a good silicon diode requires approximately 0.5–0.7 volt to forward bias or conduct current.
 - b. Below 0.5–0.7 volt, the diode may appear to block current in both directions; when placed in the diode range, a meter will put out higher voltage than barrier voltage of 0.7 volt to cause the diode to reverse and forward bias.
 - c. Both A and B
 - d. Neither A nor B
8. Which of the following statements about graphing meters is *not* correct?
- a. One of the latest diagnostic tools is a digital graphing meter used to analyze electrical waveforms produced by sensors, motors, actuators, and alternators.
 - b. Graphing meters plot an electrical value of a signal over time, displaying an easy-to-read graph with signal value on the x-axis and the time on the y-axis.
 - c. Component serviceability can be determined by analyzing the waveform or comparing it to known signals of good quality.
 - d. A Hall-effect sensor may have intermittent problems that may not be detected by the machine's onboard diagnostic system.
9. Which of the following statements about OEM diagnostic software is correct?
- a. A variety of OEM diagnostic software types are used to read serial data from a machine data link connector.
 - b. The OEM diagnostic software is used to translate the serial data into a format that can be read by the technician.

- c. More sophisticated OEM diagnostic software uses bidirectional communication between the tool and the ECM to send commands that can actuate output devices or cause the ECM to enter diagnostic routines such as performing cylinder cutout tests.
- d. All of the choices are correct.

10. Which of the following is included in the SAE J1978 requirements?
- a. Obtaining and displaying diagnostic trouble codes (DTCs)
 - b. Obtaining and displaying emissions-related data from engine parameters
 - c. Both A and B
 - d. Neither A nor B

ASE Technician A/Technician B Style Questions

1. Technician A says that self-powered test lights are like regular test lights except that they contain a 1.5-volt battery. Technician B says that self-powered test lights have to use the machine's battery power to function. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says that a popular type of LED test light is battery powered and has two LEDs—one red and the other green. Technician B says that the LED light will change brightness depending on the circuit's voltage. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says that multimeters are electrical measuring instruments combining functions of at least voltage, resistance, and amperage measurement into a single compact instrument. Technician B says that digital multimeters are the most common category of multimeters and provide numerical displays of electrical data. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
4. Technician A says that a multimeter measures resistance, continuity, voltage, and amperage. Technician B says that the multimeter can be used to measure circuit resistance in amps to determine whether amperage is within specifications. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says that before using a digital multimeter, the first task is to check that its shunts and fuses are in place and functioning. Technician B says that shunts do not

operate like fuses and do not have a maximum rating. Who is correct?

- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
6. Technician A says that the multimeter is connected in series with the circuit or component to measure the voltage dropped by the circuit resistance. Technician B says that the ohmmeter works well in testing semiconductors. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
7. Technician A says that ammeters measure the quantity of electrons flowing through a circuit per second of time. Technician B says that measuring amperage requires that the circuit be broken and the meter placed in series with the circuit so that all the current flows through the meter shunts. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says that multimeters use a thermocouple accessory to measure temperature by contact. Technician B says that heating the thermocouple produces amperage proportional to temperature. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

9. Technician A says that circuit tracers, also called wire tracers, are electronic service tools used to trace a single wire over a distance where multiple wires are bundled, shorted, or open. Technician B says that circuit tracers can identify wires deeply buried behind walls or in tightly bundled harness. Who is correct?

- a. Technician A
- b. Technician B
- c. Both Technician A and Technician B
- d. Neither Technician A nor Technician B

10. Technician A says that OEM software, along with a data link adapter, can translate the serial data from the machine ECU into a format that can be read by the technician. Technician B says that the DLC adapter may connect to the PC using a cable connected to a serial port, USB port, or wirelessly over the Internet or Bluetooth communication. Who is correct?

- a. Technician A
- b. Technician B
- c. Both Technician A and Technician B
- d. Neither Technician A nor Technician B

CHAPTER 12

Batteries and Battery Services

Knowledge Objectives

After reading this chapter, you will be able to:

- **K12001** Describe the purpose and applications of batteries.
- **K12002** Identify and describe the construction and types of lead-acid batteries.
- **K12003** Identify and describe the features of lithium, nickel-cadmium, and nickel-metal hydride batteries as well as ultracapacitors.
- **K12004** Identify and describe the purpose, operation, and application of battery types.
- **K12005** Define battery terminology, and explain battery ratings.
- **K12006** Recommend the correct size, type, and rating of replacement batteries.
- **K12007** Identify and explain chemical reactions in lead-acid batteries during charging and discharging.
- **K12008** Identify and explain the operation of battery isolators, low-voltage disconnect devices, charge equalizers, and battery management systems.
- **K12009** Identify safety equipment and safe work practices for servicing batteries.
- **K12010** Identify and describe failure modes of batteries.
- **K12011** Recommend battery replacement based on battery testing procedures.
- **K12012** Identify and describe the process of battery recycling.

Skills Objectives

After reading this chapter, you will be able to:

- **S12001** Inspect, clean, fill, or replace the battery, battery cables, clamps, connectors, hold-downs, and battery boxes.
- **S12002** Perform a battery state of charge test.
- **S12003** Perform a conductance test on a battery.
- **S12004** Perform a load test on a battery.
- **S12005** Charge a commercial battery.
- **S12006** Jump-start a commercial vehicle.
- **S12007** Measure parasitic draw on a battery.
- **S12008** Identify and test a low-voltage disconnect.

Attitude Objectives

After reading this chapter, you will be able to:

- **A12001** Locate and follow correct safety procedures and use personal protection equipment when servicing electric motors.
- **A12002** Acquire correct service information for testing and maintenance of batteries.

► Introduction

Batteries are the most essential component in a vehicle's electrical system. Not only do batteries provide starting power for engines and operating electrical accessories, they play a critical role in proper operation and longevity of many other electrical components. The recent development of medium- and heavy-duty hybrid-drive vehicles adds to the battery's list of jobs: in addition to their traditional functions, batteries must now supply energy to electric drive motors and help recover energy during braking. Today's technicians need to know more than ever about the various types of batteries they will encounter and how those batteries work, as well as how to maintain, test, and work safely with them.

► What Is a Battery?

K12001

Batteries are not devices that store electricity. In reality, they convert chemical energy into electrical energy, and vice versa. When connected to an electrical load such as a light or electric motor, chemical reactions taking place inside the battery force electrons from the negative to the positive terminal of the battery, through the load. Flow of electricity ends when the electrical loads in the circuit deplete the battery's chemical energy. The single direction in which electrons flow during discharge means a battery is a source of direct current (DC).

► Battery Classifications

K12004

The industry classifies batteries into two basic categories: primary and secondary. In a **primary battery**, chemical reactions are not reversible, and the battery cannot be recharged. In contrast, **secondary batteries** are rechargeable (**FIGURE 12-1**). By reversing the direction of current and pushing electricity back into the battery, the “galvanic” chemical reactions that originally produced electrical current renew, allowing the secondary battery to be used over and over again. Secondary batteries based on the principles of galvanic reaction are the most practical for use in heavy equipment applications because they can

FIGURE 12-1 Secondary batteries can be repeatedly charged and discharged.

be used repeatedly. (Technically a **galvanic reaction** is where the battery generates electricity when two dissimilar metals are placed in an electrolyte.)

Galvanic Batteries

The term “battery” more accurately refers to a collection of electrochemical cells connected together. A medical experimenter named Galvani discovered more than two hundred years ago that two dissimilar metals placed in an electrolyte produce electricity. **Electrolyte** refers to any liquid that conducts electric current. For example, pure water does not conduct current. Tap water, however, does. That's because tap water often contains minerals and chlorine, which enable the movement of electronics, so tap water is an electrolyte. Water containing salt, acids, or alkaline substances is an even better conductor of electricity. The dissimilar metals placed in an electrolyte form electrodes, which are the points of the battery that create the positive and negative electrical poles. The chemical action between the electrolyte and electrodes strips electrons from one metal electrode and adds electrons to another electrode. This process develops the battery's polarity. After Galvani, another experimenter named Volta built the first battery when he alternately stacked copper and zinc plates separated with a piece of saltwater-soaked cardboard. Volta named it a “voltaic pile” after demonstrating its electrical properties.

You Are the Mobile Heavy Equipment Technician

As a technician with many years of service in your heavy equipment dealership, management has asked you to join the health and safety committee. Your experience working in a shop environment has made you conscious of the importance of using safe working practices and making workplace safety a top priority. One of the initiatives of the health and safety committee is implementing the best safety practices to use while working with batteries. In fact, development of an in-house policy in addition to OSHA requirements originates from a recent incident where an exploding battery injured one worker who was jump-starting a vehicle. As you consider the various procedures that your fellow workers should follow in the shop to avoid any accidents, injuries, or damage to customer vehicles and property, ask yourself:

1. What are the major safety issues related to working with batteries?
2. What protective equipment should we use when filling batteries or checking cell electrolyte with a hydrometer?
3. Can we outline a sequence of actions a technician should follow when jump-starting a vehicle?

A battery consists of two dissimilar metals: an insulator material separating the metals and an electrolyte, which is an electrically conductive solution. The material from which the electrodes are made and the type of electrolyte determine the voltage potential of a battery. The area of the plates making up each positive and negative electrode determines the capacity or amperage of a battery.

The traditional heavy equipment battery type is the lead-acid battery. It is available in a variety of sizes and designs to meet the requirements for various applications. For example, the battery for starting a vehicle's engine is different from the battery for a bulldozer. Each requires unique design and construction characteristics based on its applications. Batteries for having equipment using diesel engines supply high amperage to the starting motor for short periods of time. In contrast, a deep cycle battery's current is almost completely depleted, supplying smaller, continuous loads over longer periods of time.

► TECHNICIAN TIP

We can observe galvanic reactions in many places. Corrosion is one example of a galvanic reaction. The cooling system of an engine contains water (an electrolyte) and dissimilar metals like copper injector tubes, cast iron blocks, aluminum water pump housings, and so on. Metals losing electrons disintegrate while other metals remain unaffected. However, one can easily observe the electron transfer between the metals through coolant if you place a voltmeter with one lead in the coolant and the other on the engine block or other metal part. (Corrosion inhibitors in the cooling system work by minimizing the loss of electrons from metals.) Trailer manufacturers insulate aluminum side plates with a piece of nonconductive nylon or insulating tape to isolate the plate electrically from steel I-beams supporting the floor. For the same reason, when manufacturers place aluminum and steel disc wheels together on the same wheel end, they separate them with a plastic or nylon gasket to minimize the corrosion galvanic reactions cause.

Maintaining a strong negative ground on a vehicle minimizes chassis corrosion that galvanic reaction causes. You may notice most corrosion takes place at positive battery posts and at the end of non-insulated, positively charged wires. This happens because positively charged wire ends and battery posts are deficient of electrons. Oxygen and molecules in road salt are examples of substances that easily provide those electrons to electron-depleted metal and then bind electrically to positive terminals and wire ends. Some military equipment and off-road heavy equipment from Europe use a positive ground system to protect the exposed wiring on starters, alternators, and wiring harnesses from the effects of corrosion. Electrical system reliability is enhanced at the expense of chassis corrosion, which instead attacks large, heavy steel chassis components that can better withstand corrosion.

Because heavy equipment could have either a 12 V or 24 V system and all mobile equipment batteries are 12 V, this means that to power a 24 V system at least two batteries have to be connected together. You may find four or more batteries connected together on some machines. Therefore the term "battery system" is used. A battery system is needed for the following reasons:

1. To provide electrical energy to power electrical devices if the machine's engine is not running

2. To provide electrical energy to the starter to crank the engine
3. To provide electrical energy when the engine is running if the alternator can't satisfy electrical demand
4. To act like an accumulator to store and stabilize voltage

Thirty or 40 years ago, 6 V batteries were fairly common for heavy equipment electrical systems, but at least 99% of the machines today only use 12 V batteries. However, if the vehicle has more than one battery, it depends on how the batteries are connected as to how much voltage comes out of the battery system. Two 12 V batteries hooked in parallel (positive to positive and negative to negative) still produces 12 V, whereas two 12 V batteries connected in series produce 24 V. **FIGURE 12-2** demonstrates how two 12 V batteries are connected to make either a 12 V or a 24 V system. If you are replacing a set of batteries, make a sketch before removing any cables. Always disconnect and connect ground cables first and last, respectively.

Heavy equipment uses several types of batteries. Identify the conventional type by the removable caps over each cell that allow the technician to test and top up the electrolyte. The design of this style of battery allows a loss of electrolyte due to gassing that occurs when the battery charges. This style of battery is becoming increasingly less popular because of the higher maintenance required.

Another style is the low-maintenance battery that has removable caps; but because of different materials used for its plates, which reduce the gassing during the charging process, it rarely requires maintenance.

The most popular style of battery is the maintenance-free battery that is sealed for life. There is no way of checking or testing its electrolyte, and because of its different plate

FIGURE 12-2 A. Batteries connected in a parallel configuration. B. Batteries connected in series.

material, it produces very little gas and therefore doesn't lose electrolytes.

Slowly gaining popularity are gel cells and glass mat batteries. These are a more expensive version of a maintenance-free battery that features a gel-type electrolyte and are supposed to be very durable. These batteries, however, come at a price premium and have special requirements when charging or boosting is required. We discuss the different types of batteries in detail later in this chapter.

SAFETY TIP

If you suspect a battery is frozen, *do not* boost or charge it until it is warmed up. If a battery's electrolyte freezes, it will likely distort the plates, which could cause an explosion if charged or boosted.

Electrolyte or battery acid is a very dangerous substance. If you get any on your skin, you should immediately flush the affected area with water. Always wear PPE (personal protection equipment). Baking soda neutralizes battery electrolyte. Every shop and service truck should have a box on hand. A solution of diluted ammonia and water also is effective and does not leave a powdery residue.

Battery Functions

Traditionally heavy vehicles have batteries similar to those we see in **FIGURE 12-3**, to provide starting current and operate electrical accessories if the engine is not running. And although supplying electric current for starting is the most obvious function for a battery, it's important to consider the

other jobs the battery performs that are critical to proper electrical system operation. Battery functions on heavy-duty vehicles include those listed here:

1. **Providing electrical energy to the vehicle whenever the engine is not running.** When the engine is running, a properly designed and operational charging system supplies electrical current to meet most electrical demands and charge the battery. For today's heavy vehicles and equipment, the limitation on, or even elimination of, engine idle means batteries have to supply electrical current for prolonged periods to devices such as electrohydraulic pumps for hydraulic brakes, power steering, coolant pumps, and air-conditioning compressors. Heavy-duty equipment hybrid electric vehicles are now more commonplace. They are dependent on battery-supplied electrical current to operate all electrical devices, including electric drive motors and all electrical accessories, for much longer periods than conventional vehicles using accessories driven by an internal combustion engine.
2. **Providing electrical energy to operate the starter motor, ignition, and other electrical systems during cranking.** Other devices, such as hydraulic or air starter motors, could be used to start engines. However, even electronically controlled diesel injection systems require current to operate during cranking. With electric starter motors, batteries must be capable of delivering high current flow for short periods of time. Batteries used for cranking purposes have unique construction features and are commonly termed **starting, lighting, and ignition (SLI) batteries**. Diesel-powered equipment use multiple batteries, called a bank of batteries, connected in series or parallel to produce adequate starting current.

FIGURE 12-3 Batteries traditionally supply starter current and power to run electrical accessories when the engine is not running.

3. **Providing extra electrical power whenever power requirements exceed the output of the charging system.** High current demands are occasionally placed on the electrical system. For example, when an engine is idling, the charging system current output is low. Current flow to blower motors operating at high speed for heating or air conditioning systems, lighting circuits, and other electrical devices can exceed the output of the charging system. To maintain proper operation of these circuits, the batteries should be sized to provide adequate current.
4. **Storing energy over long periods of time.** Even when vehicles are not in use for extended periods of time, the battery is still expected to deliver current to start a vehicle. Today, heavy vehicles and equipment have numerous **key-off electrical loads**. These are current draws on the battery when the ignition is off. Also called **parasitic draw**, this battery current is required continually to operate vehicle security systems, GPS devices, and computer memory for multiple electronic control modules, entertainment systems, and other electrical accessories requiring constant power.
5. **Acting as an electric shock absorber for the vehicle's electrical systems.** The use of microprocessors and microcontrollers in almost every vehicle system makes today's heavy equipment sensitive to fluctuations in voltage. Operating on current in the millivolt range, stray and uneven electrical current can interfere with and even damage the operation of these sensitive electronic devices. The operation of common components such as alternators, switches, and electrical devices with inductive coils regularly produces this type of electrical interference. Batteries help minimize fluctuations in a vehicle electrical system by absorbing and smoothing variations in electrical current.
6. **Operating electric drive traction motors.** The development of hybrid electric vehicles (HEVs) has created new functions in addition to the traditional purposes of batteries. In HEVs, batteries must provide even higher amounts of current for longer periods of time to operate electric traction motors

that propel the vehicle, as illustrated in **FIGURE 12-4**. HEVs require new battery chemistry and construction to extend battery life, reduce weight, increase energy density, charge more quickly, and discharge and charge more frequently while delivering higher amounts of current flow for extended periods of time. Batteries must accomplish these goals in the harsh operating environment and duty cycle of heavy equipment. At the same time, batteries must perform with greater and more consistent reliability than ever before. New types of batteries and battery management systems help meet these operational demands.

► Types and Classifications of Batteries

KI 2002

Batteries are generally classified by application. In other words, batteries are classified according to what they are used for and how they are made. Batteries are also classified according to the type of plate materials and chemistry used to produce current. Until recently, lead-acid batteries have been the only battery technology used in heavy equipment. Although the search for more durable and reliable lead-acid batteries has brought innovation to that category of batteries, the development of hybrid-drive vehicles has resulted in the introduction of different types of battery technology, such as nickel-metal hydride and lithium batteries. We discuss other chemistries in the Advanced Battery Technologies section.

Lead-Acid Batteries

Lead-acid batteries have been developed commercially for over 130 years and are a mature, reliable, and well-understood technology. They are also the most common battery used in the heavy equipment industry. Lead-acid batteries deliver high rates of current with a higher tolerance for physical and electrical abuse compared to other battery technology. These batteries

FIGURE 12-4 Batteries are now required to provide current to electric traction motors and store current produced during regenerative braking.

hold a charge well and when stored dry—without electrolyte—the shelf life is indefinite. Relatively simple compared to other battery technologies, lead-acid batteries are also the least expensive to manufacture in terms of cost per watt of power.

Contributing to the popularity of lead-acid batteries is the fact that they are available in a wide range of sizes and capacities from many suppliers worldwide. Manufacturers classify lead-acid batteries by their construction and application. Six types of construction are found on heavy equipment, but the basic chemical action is identical in all, including these:

- Flooded cell, including low maintenance (**FIGURE 12-5**) or maintenance free.
- Deep cycle flooded cell.

Valve-regulated lead-acid (VRLA) batteries, also called **sealed lead-acid (SLA)** or recombinant batteries, like the one shown in **FIGURE 12-6**, is a category that includes the following types:

- Flooded
- Gel cell
- Absorbed glass mat (AGM)
- Spiral cell (Optima® batteries)

FIGURE 12-5 A typical low- or no-maintenance SLI battery.

FIGURE 12-6 A VRLA sealed battery.

Starting, Lighting, and Ignition Batteries (SLI)

Among the categories of lead-acid batteries, the most common use is for starting, lighting, and ignition (SLI). SLI batteries are designed for one short-duration deep discharge of up to 50% depth of discharge (DOD) during engine cranking. Discharging is quickly followed by a charging period, and the battery maintains a full charge. The operating requirements of an SLI battery are very different from those for **traction batteries** in hybrid electric vehicles, which are rechargeable batteries for propulsion. Although identical in appearance, SLI batteries are also constructed differently than deep cycle batteries.

Deep Cycle–Deep Discharge Batteries

Deep cycle batteries deliver a lower, steady level of power for a much longer period of time than SLI-type batteries. Furthermore, battery plate construction and charging and discharging characteristics of deep cycle batteries are different from SLI-type batteries. In heavy vehicles, deep cycle batteries supply current to constantly powered accessories like driver and vehicle communication devices. Deep cycle batteries also supply power to wave inverters, which in turn supply alternating current (AC) to appliances such as refrigerators, TVs, or laptop chargers. In addition, deep cycle batteries power accessory lighting, electric winches, and tailgates. This type of battery typically uses a battery isolator system that separates the main vehicle electrical system from the deep cycled battery circuit. The charging system replenishes the deep cycle battery charge, but the main vehicle electrical circuits cannot access it.

Battery Construction and Operation

The basic components of a battery are its case, terminals, plates, and electrolyte. Even though the construction of batteries can vary depending on their type and application, these basic components remain the same. It is important that technicians select the correct size, type, and construction for the application. Before selecting a battery for a particular application, the technician needs to answer a number of questions. For example:

- Is the starting battery or a deep cycle battery supplying electrical accessories?
- Is the battery working in extremes of temperature?
- Is it a high-vibration environment?
- What electrical load does the battery need to supply and for how long?
- What case and terminal configuration is required?

This section examines battery construction and discusses how those questions and their answers aid in the selection of the correct battery for an application. This section also explains the charge and discharge cycle of a battery.

Flooded Lead-Acid Batteries

Flooded lead-acid batteries refer to battery cell construction where the electrodes are made from thin lead (Pb) plates

FIGURE 12-7 Typical plate arrangement in a wet cell battery.

submersed in liquid electrolyte. Two dissimilar compositions of lead form the positive and negative electrodes (**FIGURE 12-7**). Sponge lead, which is lead made porous with air bubbles, forms the negative plate. Lead dioxide (PbO_2) is the active material of the positive plate.

The electrodes and electrolyte of a lead-acid battery cell produce 2.1 volts. Connecting cells together in series allow a variety of output voltage. This means a fully charged 12-volt battery, in fact, produces 12.6 volts with no electrical loads by connecting six cells together. Twenty-four-volt systems are commonly used in heavy-duty off-road equipment and by the military. These combinations of 12-volt batteries connected in series produce 24 volts.

Adding Amperage and Voltage

The amount of amperage a battery supplies is a function of the surface area of the plates. To increase the amperage deliverable from a battery, the surface area or number of plates must increase. Plates connect together in parallel within each cell to increase the amperage or capacity of a battery. Positive plates connect only to other positive plates within each cell, and likewise with negative plates. Plate straps for each cell set of positive and negative plates join through a connector to another strap in adjacent cells. There are two rows of these intercell straps and connectors. In a 12-volt battery, six positive plate straps link in series to six negative plate straps, alternating a positive strap to a negative strap as each cell is connected (**FIGURE 12-8**). The last cell in the series circuit contains one of the battery posts, either positive or negative. Strap connections between the cells are made either through the cell partitions in the case or over the top of the partition.

Separator Plates

To prevent the battery positive and negative plates from touching and short-circuiting, manufacturers place separator plates between each plate in every cell. Separator plates are very thin, porous, glass-fiber materials that allow electrolyte to diffuse freely throughout the cell and at the same time prevent plate contact.

FIGURE 12-8 Interconnections between all six cells in a battery, showing the most negative and positive points of the battery.

► TECHNICIAN TIP

Manufacturers design and construct SLI batteries to deliver a short, high-amperage burst of current for starting. Using a deep cycle battery to replace an SLI battery can cause damage to starting motors and conductors through a condition known as low-voltage burnout. This happens when voltage drops very low while supplying high cranking amperage to the starting motor. Because the deep discharge battery cannot maintain as high an output voltage, the excessive amperage produces resistance and heat in motors, cables, and connection windings, leading to burnout.

Deep Cycle Versus SLI Battery Construction

Manufacturers design SLI batteries to produce a quick burst of energy for starting and should not be discharged less than 50% before recharging. Deeply discharging SLI batteries dramatically shortens their service life. Ideally, the longest service life is achieved when this battery is discharged no more than 5% and quickly recharged (**FIGURE 12-9**).

In contrast, deep cycle batteries are made for deep discharging by continuous but light electrical loads until completely

FIGURE 12-9 Deep discharging a battery shortens battery life.

Comparison of Deep Cycle to SLI Battery of the same dimension

FIGURE 12-10 An SLI battery uses thinner plates.

discharged. To optimize SLI battery characteristics, plates are thin so that more plates fit in each cell. More and thinner plates translate into higher available amperage due to increased plate surface area. However, continuous discharge of SLI batteries for prolonged periods of time causes the current flow to overheat, distort, and warp the thin plates. Similarly, charging SLI batteries from a deeply discharged state can cause plates to overheat, dramatically shortening battery life. The primary difference between deep cycle batteries and SLI is the thickness of the plates (**FIGURE 12-10**). Deep cycle plates are thicker to resist distortion during a discharge/charge cycle. However, thicker plates mean fewer plates compared to an SLI battery with identical dimensions. Thicker plate batteries also have higher resistance during high-amperage charging and discharging in comparison to SLI batteries.

Electrolyte

Lead-acid battery electrolyte is a mixture of 36% sulfuric acid and 64% water. The specific gravity of water is 1.000. (**Specific gravity** is a measure of density.) Sulfuric acid has a specific gravity of 1.835, which means it is much heavier than water.

Combined, the sulfuric acid and water solution has a specific gravity of 1.265. This makes it an electrolyte 1.265 times heavier than plain water. During charging and discharging, the specific gravity of the electrolyte changes. When discharging occurs, sulfate from the sulfuric acid enters both positive and negative plates. Oxygen also leaves the positive plate and combines with hydrogen left around in the electrolyte by the departing sulfate. This means the electrolyte has increasingly more water content and less acid during discharge, as **FIGURE 12-11** illustrates. The process reverses during charging when sulfate is electrically driven from the plates and reenters the electrolyte. Measuring the specific gravity or density of an electrolyte, therefore, is a good measure of battery state of charge (SOC).

Manufacturers can make flooded cell batteries with or without an electrolyte. Dry batteries (without electrolyte) can be stored on the shelf for extended periods without the fear of sulfation and are lighter to transport. For this reason, electrolyte is often only added to the battery at the point of sale.

When the specific gravity of battery acid is too low, such as when a battery is discharged, it may freeze in colder climates. An electrolyte that has lost water and is therefore

FIGURE 12-11 Electrolyte water and acid mixture for charged and discharged batteries.

overconcentrated with acid can accelerate corrosion of battery grids to which lead plate material is bonded.

It is important to note that sodium bicarbonate (baking soda, not baking powder) is an effective way to neutralize electrolyte spills. Using a power washer, for example, reduces the concentration of acid but does not neutralize it. Squirting a mixed solution of ammonia and water on spilled battery acid also neutralizes the acid. Water and ammonia also evaporates, leaving no mess to clean up.

Technicians can use a squeeze bulb and float-type hydrometer, like the one in **FIGURE 12-12A**, to measure the density or the specific gravity of liquids. Technicians can also use it to measure the specific gravity of batteries. A refractometer is an optical device that measures the density of coolant and battery electrolyte. When a drop of liquid is placed beneath the lens of the device and then held up against a bright light source, a graduated scale in the viewfinder indicates the battery's specific gravity. **FIGURE 12-12B** shows a refractometer. **TABLE 12-1** indicates the various specific gravity and voltage readings for flooded lead-acid batteries. Electronic hydrometers enable faster, temperature-compensated measurement of the battery's state of charge. Remember that battery acid is highly corrosive, so when using these devices, properly protect yourself by wearing eye protection, a rubber apron, and acid-resistant gloves, particularly when handling electrolyte.

FIGURE 12-12 A. Typical hydrometer. B. Refractometer.

TABLE 12-1 State of Charge as Indicated by Specific Gravity and Voltage Reading for Flooded Cell Batteries*

Open Circuit Voltage	Specific Gravity	Percentage of Charge
12.65 or greater	1.265 (minimum)	100%
12.45	1.225	75%
12.24	1.190	50%
12.06	1.155	25%
11.89	1.120	0%

*AGM voltages will differ.

Battery Cases

The battery case is usually made of polypropylene. Ribbing and irregular features on the outside of the case increase the length of resistive electrical conductive pathways made when dirt and water accumulate on the case. These accumulations can allow current to drain from the battery posts. Each of the six cells in a 12-volt battery is sealed, and electrolytes cannot move between cells. A gap between the plates and the bottom of each cell forms a sediment trap, as **FIGURE 12-13** illustrates. The trap collects plate material that sheds during operation. Vibration and deeply discharging a battery accelerate the loss of plate material and reduce the battery's capacity. Without the trap, plate material accumulates and potentially short-circuits the plates, leading to rapid self-discharge of the battery.

During charging and discharging, the breakdown of water through a process called **hydrolysis** causes batteries to produce hydrogen and oxygen gas. These gases require venting and are an explosion hazard. In older flooded batteries, each cell had a cap to vent gases, add water to the electrolyte level, and permit the technician to inspect the electrolyte with a hydrometer.

FIGURE 12-13 Typical sediment chamber in a flooded cell battery.

Low-maintenance batteries use a small, single vent near the top of the battery. The technician adds extra electrolyte to these batteries to compensate for water loss over the lifetime of the battery. Low-maintenance batteries have advanced plate material that result in less water loss than conventional flooded batteries. Nonetheless, a removable plug still allows access to the electrolyte during testing and servicing.

► Sizing and Terminal Configuration

KI 2006

Batteries for heavy equipment are available in a wide variety of sizes. Manufacturers build their batteries to an internationally adopted Battery Council International (BCI) group number. BCI group numbers are established according to the physical

case size, terminal placement, terminal type, and polarity. For example, battery terminals used in medium- and heavy-duty applications use a top post, threaded stud, or “L” terminal, with combinations of each of these types. **TABLE 12-2** classifies various heavy-duty battery groups. Other designations relate to the battery terminal configuration, which refers to the shape and location of the positive and negative terminals on the battery, as **FIGURE 12-14** illustrates. Different types of battery posts are also available for batteries, including top post, threaded stud, side terminal, or “L” terminal, as well as combinations of each of these types.

► TECHNICIAN TIP

To help identification and prevent incorrect connection to post-type batteries, the positive terminal is 1/16" (1.6 mm) larger than the negative terminal. Because terminals are only soldered to the cell straps and

TABLE 12-2 Heavy-Duty Commercial Batteries Groups (12-VOLT)

anchored by the polyethylene case, they are vulnerable to damage if abused. Prying and hammering on posts are common types of abuse that break the seal between the post and case and damage the connection to the plate strap.

► Battery Ratings

K12005

The electrical capacity of a battery is the amount of electrical current a lead-acid battery can supply. The BCI and the Society of Automotive Engineers (SAE) establish common battery capacity ratings that North American manufacturers use. Technicians will encounter other rating systems depending on the origin of the vehicle and on some testing equipment, including the following:

- Japanese Industrial Standard (JIS)
- EN (European Norms) Standard
- DIN (Deutsches Institut für Normung)
- IEC (International Electrotechnical Commission) Standard

Several methods used to rate lead-acid battery capacity. The three most common are cold cranking amps (CCAs), cranking amps (CAs), and reserve capacity. **Cold cranking amps (CCAs)** is a measurement of battery capacity, in amps, that a battery can deliver for 30 seconds while maintaining a voltage of 1.2 volts per cell (7.2 volts for a 12-volt battery) or higher at 0°F (−18°C) (**FIGURE 12-15**). **Cranking amps (CAs)** measure the same thing, but at a higher temperature: 32°F (−0°C). A 500 CCA battery has about 20% more capacity than a 500 CA battery.

Reserve capacity is the length of time, in minutes, a battery discharges under a specified load of 25 amps at 26.6°C (80°F) before battery cell voltage drops below 1.75 volts per cell (10.5 volts for a 12-volt battery). This measure is modeled on estimates of how long an automobile could be driven after an alternator fails with electrical loads from headlights and other loads before the ignition system fails.

Amp-hour is a measure of a battery's capacity. Specifically, it is a measure of how much amperage a battery can continually

supply over a 20-hour period without the battery voltage falling below 10.5 volts. Amp-hour is measured at 80°F (26.7°C)—the temperature at which lead-acid batteries perform best. A battery with a 200 amp-hour rating delivers 10 amps continually for 20 hours (20 hours × 10 amps). This is an important rating when selecting a deep cycle battery.

► TECHNICIAN TIP

Early heavy-duty equipment vehicles with minimal electrical loads used 6-volt batteries for a 6-volt electrical system. In the 1950s, 12-volt systems and batteries became widely used. 24-volt systems are made from combinations of 12-volt batteries connected in series to produce 24 volts. Operating with higher voltages means less amperage flows through electrical circuits and connections yet they maintain the same power levels. With less amperage traveling through conductors, the reliability of the vehicle's electrical system improves because connections and cables do not heat nearly as much from high-amperage flow. The size of components and wire diameters are reduced as well.

Multi-Battery Configurations

Batteries can be connected together to supply either more amperage or more voltage. Diesel engines, which require high cranking torque, either connect batteries in parallel, like those in **FIGURE 12-16**, to supply more cranking amperage, or in series to supply higher voltage. For example, if two 600 CCA 12-volt batteries are connected in parallel, the batteries' potential output is 1200 CCA at 12 volts. If the batteries are connected in series, we add the batteries' voltage output together even though the cranking amperage remains the same. This means if two 600 CCA 12-volt batteries are connected in series, the batteries' potential output is 600 CCA at 24 volts.

Battery Selection

Factors that determine the battery rating required for a vehicle include those listed here:

- Current needed for key-off loads
- Current needed for operating electrical accessories
- The engine type (diesel or spark ignited)
- The engine size
- Climate conditions under which equipment must operate

In cold weather, battery power drops drastically because the electrolyte thickens and cold temperatures slow chemical activity inside the battery. Cold weather also makes engines harder to crank due to increased resistance from oil thickening. It is calculated that engine resistance increases between 50% and 250% in the winter compared to the summer, as **FIGURE 12-17** illustrates. Simultaneously, available battery current can drop by as much as 75%. As batteries age, their capacity drops too.

BCI estimates diesel engines require 220–300% more battery power than a similar gasoline engine. A typical 15L diesel engine today uses approximately 10,000 watts of current (or close to 12 horsepower) during cranking and initially needs 15,000 watts, or 20 horsepower. Vehicle manufacturers make

FIGURE 12-15 The battery's label indicates ratings. **A.** Date code. **B.** Battery ratings CCA, CA, and RC.

FIGURE 12-16 Typical battery bank configurations.

FIGURE 12-17 As temperature drops, engine rotation resistance increases, and battery chemical reactions slow.

recommendations about the capacity of batteries. The CCA rating of the battery is the most important rating considered when selecting batteries. Although selecting a battery with excessive current capacity might seem like a good idea, it is not. Extra capacity is expensive and high-amperage capacity available from batteries can lead to premature starter drive failure from excessive torque and damage from excessive amperage through starting circuit connections.

Equipment manufacturers use a number of variables when calculating battery capacity, but the most significant one is battery voltage at the end of engine cranking. Generally batteries are sized to ensure a minimum cranking voltage of no

less than 10.5 volts after three consecutive cranking periods of 30 seconds, with a 2-minute cooldown period between each cranking period.

► TECHNICIAN TIP

Equipment with excessive battery capacity (too many CCAs) can lead to premature failure of the starter motor and starter drive due to excessively high torque. Excessive battery CCA increases the amperage through cables, connections, and starter circuit components, causing damage from resistance heating. However, inadequate battery capacity shortens battery life from deep discharging. Equipment may even fail to start in cold weather or as batteries age. Starter motors, cables, and circuits can be damaged from low-voltage burnout caused by undersized batteries.

Internal Resistance of Batteries

All electrical devices have internal resistance—even batteries. Not all battery types have the same internal resistance, however. A battery's internal resistance depends on the types of materials the manufacturer used to make the plates and the chemical composition of the electrolyte. A battery's internal resistance determines how quickly a battery can be charged or discharged.

Batteries with a relatively low internal resistance, such as a standard lead-acid battery, can be charged quickly, and they can also be discharged quickly to supply a lot of current over a short period of time. This makes them ideal for use as starter batteries in vehicles because they can supply the high-discharge current the starter motor requires to start the vehicle. Batteries are available with a lower internal resistance than that of a lead-acid battery, such as the newer lithium batteries now in battery banks for electric and hybrid vehicles. These types of batteries are

more expensive than the standard lead-acid battery, and their lower internal resistance is generally not needed for everyday starter motor applications.

► Charging and Discharging Cycle

KI 2007

Battery plates are made of two different compositions of lead fabricated from paste bonded to lead alloy grids. The negative plate uses lead (Pb), and the positive plate uses lead peroxide (PbO_2). Antimony, calcium, or other metals are alloyed with the lead grid material to minimize corrosion that the lead acidic electrolyte can cause. Because the plates are made of dissimilar metals, the addition of electrolyte causes galvanic reactions in each cell.

In a fully charged condition, the positive plate material is predominantly lead peroxide (PbO_2), and the negative plate is sponge lead. The composition of the electrolyte is 64% water and 36% sulfuric acid. Chemical interactions between the plates and electrolyte strip electrons from the positive plate and add electrons to the negative plate, which produces a 12.6-volt difference between the battery terminals. A lead-acid battery remains in this condition without a load applied. However, due to activity of chemical reactions, a slow rate of self-discharge occurs, which eventually discharges the battery. This self-discharge rate is dependent on temperature and the selection of materials the manufacturer used during manufacturing. In hot climates, complete self-discharge is measured in weeks. In colder climates, cold slows down chemical reactions, so the self-discharge rate can take almost two years.

When a load is applied across the battery, electrons moving from the negative to the positive terminal accelerate galvanic reactions. **FIGURE 12-18A** illustrates this process. Both plates and the electrolyte composition change because of electron movement. Oxygen atoms in the positive plate move into the electrolyte while the sulfate part of the acid moves into the positive plate, changing the cell from lead peroxide (PbO_2) to lead sulfate (PbSO_4). On the negative plate, sulfate also moves into the plate material, forming lead sulfate (PbSO_4). The electrolyte

becomes less acidic and turns to water as sulfate leaves and hydrogen in the electrolyte combines with oxygen driven from the positive plate.

Galvanic reaction in a battery stops under two circumstances. One is if the electrical load is removed from the battery. This halts chemical reactions when electrons move from one battery terminal to the other. Electron movement also stops when the positive and negative plates become saturated with sulfate in a process called **sulfation**.

When charging a lead-acid battery, the chemical reactions used to produce current are reversed, restoring the plate and electrolyte to its charged condition (see **FIGURE 12-18B**). While charging, sulfate is driven from both plates back into the electrolyte. Oxygen in the electrolyte recombines with the lead in the positive plate.

The chemical action occurs by connecting a charger or an alternator (DC current), stripping the positive post of electrons and forcing them back into the negative terminal. Charging voltage needs to be sufficiently high enough to overcome a battery's natural resistance to current flow. Most charging systems maintain a maximum charging voltage of approximately 0.5 volt above battery voltage. This explains why the charging system set point for most 12.65-volt batteries is around 14.2 volts. Higher voltage battery chargers push more current into the battery at a higher amperage.

► TECHNICIAN TIP

If a battery is completely discharged, the similar chemical composition of both plates permits the battery polarity to reverse. If connected incorrectly to a charger or charging system, the battery charges up with reverse polarity. If an operator reconnects a battery with reverse polarity to a vehicle, the results are disastrous. Burnt wiring, blown fuses, and alternator damage quickly result, leading to a potential vehicle fire.

Plate Sulfation

Sulfate is driven off battery plates when charging, as **FIGURE 12-19A** shows. However, if a battery is left in a discharged state for a long period of time continually undercharged, or left partially charged,

FIGURE 12-18 A. Charging cycle. B. Discharge cycle.

FIGURE 12-19 A. Normal plate condition. B. Sulfated plate.

the soft sulfate turns to a hardened crystalline form, as **FIGURE 12-19B** shows. Hard sulfate cannot be driven from the plates.

This means the battery cannot be recharged, and the remaining active plate material develops a high resistance to charging. The latest innovation to lead-acid battery technology incorporates black-carbon graphite foam into the plate paste to prevent sulfation damage. Graphite-foam carbon increases plate strength and surface area, which translates into greater power density and durability.

Gassing

During charging and discharging, water in the electrolyte breaks into its constituent hydrogen and oxygen. This process, called **electrolysis**, releases both gases. Electrolysis through the loss of water depletes battery electrolyte. If electrolyte is too low, the plates dry out, and the increased acid concentration of electrolyte permanently damages the grids. Severe **gassing** occurs when charging voltage pushes beyond 2.4 volts or when severe discharge takes place, such as when someone lays a wrench or piece of metal across battery terminals.

Low- and No-Maintenance Batteries

The use of antimony alloy in the plate grids of conventional flooded battery technology minimizes grid corrosion and allows

these batteries to accept up to 10 times more overcharging than newer low- or no-maintenance batteries. Unfortunately, antimony-alloyed grids cause excessive gassing, resulting in substantial water loss. No- or low-maintenance battery technology solves that problem.

Introduced in the middle 1970s, no- and low-maintenance batteries reduce or eliminate the antimony content in grids. Manufacturers use calcium primarily now to replace antimony but they also use barium, cadmium, or strontium. No-maintenance batteries eliminate all the antimony, whereas low-maintenance batteries contain a reduced level of antimony content (approximately 2%). No- and low-maintenance batteries still require venting and need a large electrolyte reserve area above the plates to compensate for some water loss.

Another recent advance in grid composition involves manufacturers adding silver into the calcium-lead alloy. Silver alloy has a very high resistance to grid growth and corrosion. Thus, silver alloy significantly lengthens battery life in high-heat and severe-service conditions.

Some of the advantages of low- or no-maintenance batteries are presented here:

- Less water usage
- Less grid corrosion
- Less gassing
- Lower self-discharge rate
- Less terminal corrosion because less corrosive gas is emitted from the vents

The disadvantages of low- and no-maintenance batteries include the following:

- A lower electrical reserve capacity
- Often a shorter life expectancy
- Grid growth/expansion when exposed to high temperatures
- More quickly discharged by parasitic losses
- Difficulty accepting a boost when completely discharged

Although no-maintenance batteries contain a vent beneath the top cover, the battery tops are completely sealed. Delco, which introduced the first no-maintenance battery, uses a built-in hydrometer that has colored balls. These balls rise or fall in the electrolyte, depending on the electrolyte density, thereby providing an indication of the state of charge. To boost these batteries from a completely discharged state, a small charge is recommended for about 10 minutes to begin the hydrolytic process of breaking water into hydrogen and oxygen. After that, the batteries are capable of receiving a higher rate of charge.

Low-maintenance batteries may look completely sealed, but they usually have a means of adding water if required. Often the caps are concealed under a plastic cover that the technician removes to reveal cell caps that can be unscrewed (**FIGURE 12-20**).

The latest and most advanced commercial vehicle battery technology are **absorbed glass mat (AGM) batteries**. AGMs provide improved safety, efficiency, and durability over existing battery types. The electrolyte absorbs into a fine glass mat, as **FIGURE 12-21** shows, preventing it from sloshing or separating

FIGURE 12-20 The spiral cell Optima battery is an example of an AGM-type battery.

FIGURE 12-21 AGM batteries trap and recombine oxygen and hydrogen gases inside the glass mat next to the plates.

into layers of heavier acid and water. The fiber first helps by enhancing gas recombination rather than simply venting gas to the atmosphere and lowering electrolyte levels. AGM material also possesses low electrical resistance. As a result, it can deliver more cranking amperage and absorb up to 40% more charging current than conventional lead-acid batteries, leading to faster charging. Higher cell voltage and sensitivity to overcharging requires special service consideration.

► Advanced Battery Technologies

KI 2003

The demand for advanced battery technology in heavy equipment vehicles is growing. Several key factors are at play in determining which application of a variety of battery technologies to use on heavy equipment vehicles:

- Energy density (**FIGURE 12-22**)—expressed in watt-hour per kilogram (Wh/kg) and watt-hour per liter (Wh/l)

Energy:
Watt-Hours/Weight
(Endurance)

FIGURE 12-22 Comparing the energy density of various battery technologies. Lithium-ion produces the greatest amount of energy for the longest time per kilogram of weight.

- Life span—measured by the number of charge/discharge cycles as a function of depth of discharge
- The state of charge window—the availability of usable battery voltage
- Cost in dollars per kWh

Types of Advanced Batteries

The major battery technologies used in hybrid heavy equipment vehicles are nickel-metal hydride (NiMH), lithium, and lead-acid. Each technology has distinct capabilities, which we discuss in this section. **TABLE 12-3** compares the capacities of different battery types.

Nickel-Metal Hydride (NiMH) Battery

Manufacturers use **nickel-metal hydride (NiMH) batteries** not only in consumer electronics but also as a preferred battery chemistry for hybrid-drive vehicles. That is because NiMH batteries are relatively lightweight and have high power output and long life expectancy. Heavy-duty hybrids use these. NiMH batteries provide twice the energy storage of lead-acid by weight, but only half the power output—at 1.2 volts/cell compared to 2.1 volts/cell for lead-acid batteries. As **FIGURE 12-23** illustrates, a unique alloy of rare earth metal, which has an unusual ability to absorb hydrogen, forms the metal hydroxide negative electrode. The positive electrode is made of nickel oxide (NiOH_2). The electrolyte is composed of potassium hydroxide, which is an alkaline.

Lithium-Ion Batteries

Lithium-ion batteries were developed for use in the early 1990s. Lithium-ion (Li-ion) batteries are secondary batteries and are not the same as disposable, primary-type lithium batteries, which contain metallic lithium.

TABLE 12-3 Comparison of Properties for Different Battery Chemistries

Range Battery Type	Voltage/cell	Cost Watt/hour	Energy Density		
			Watt-hour/kg	Joules/kg	Watt-hour/liter
Lead-acid	2.1 volts	Lowest = 1	41	146,000	100
NiMH	1.2 volts	6 times lead-acid	95	340,000	300
Li-Ion	~ 4.0 volts	25 times lead-acid	128	460,000	230
Ultra capacitors	~ 2-3 volts	4-5 times lead-acid	30-60	—	—
Diesel Fuel	—	—	—	—	10,942

**FIGURE 12-23** Chemical reactions in an NiMH type battery.

Like conventional batteries, Li-ion batteries have electrodes and use an electrolyte. Unlike conventional batteries, the chemical reactions in Li-ion batteries are not galvanic, and the material separating the electrodes is a gel, salt, or solid material. With no liquid electrolyte, Li-ion batteries are immune to leaking. Currently there are dozens of different cell chemistries used to produce lithium-ion batteries. The voltage, capacity, life cycle, and safety characteristics of a lithium-ion battery can

change dramatically depending on the choice of material for the anode, cathode, and electrolyte. Regardless of their specific chemistry, lithium batteries have a higher energy density than other battery types such as lead-acid, nickel-cadmium, and NiMH, as **FIGURE 12-24** shows.

Popular Li-ion chemistries incorporate electrodes made from lithium combined with phosphate, cobalt, carbon, nickel, and manganese oxide.

Lithium-phosphate batteries ($LiFePO_4$ chemistry) are the most common lithium battery chemistry for use in heavy-duty hybrid and electric vehicles. The advantages to using lithium-ion batteries in vehicles include the following:

- The best power-to-weight ratio compared to other battery technology.
- Li-ion batteries have higher cell voltages, with as much as 5 volts in some designs. A typical cell voltage averages between 3.3 and 4.2 volts, which means fewer Li-ion cells are required to form high-voltage batteries. It also translates into fewer vulnerable and resistive cell connections and reduced electronics in the battery management system. One lithium cell can replace three nickel-cadmium (NiCad) or NiMH cells, which have a cell voltage of only 1.2 volts.

**FIGURE 12-24** Comparing different lithium-ion battery energy densities with other battery types.

- Li-ion cells maintain a constant voltage for over 80% of their discharge curve. In comparison, conventional lead-acid batteries maintain voltage until only 50% discharged. Therefore, in a Li-ion battery, more stored energy is usable over longer periods to supply electrical accessories or to crank an engine frequently and faster, before becoming effectively discharged. It also means that a smaller capacity battery can supply a vehicle's power needs.
- Li-ion batteries operate well over wide temperature ranges: -60°F (-51°C) to 167°F ($+75^{\circ}\text{C}$). Cold slows down chemical reactions in other battery technology. However, cold temperatures do not slow the nongalvanic reactions in Li-ion batteries.
- Charging characteristics of Li-ion batteries are superior to other batteries. In consumer electronic devices, Li-ion batteries have demonstrated the capacity to recharge as much as 90% within 5 minutes. That speed is a distinct advantage for the efficiency of regenerative braking used by electric and hybrid electric vehicles. Once charged, Li-ion batteries self-discharge at a very low rate.
- Li-ion batteries have low internal resistance and can discharge their current four times faster compared to lead-acid batteries. In addition, high discharge and charge rates do not wear out a Li-ion battery to the extent that charge and discharge cycles reduce the lifespan of other types of batteries. Currently, typical Li-ion batteries can withstand 1,200 charge-discharge cycles in comparison to 500–800 cycles for lead-acid and 1,500 for NiMH, as the chart in Figure 12-24 shows. Li-ion batteries last for millions of micro-discharge cycles. A micro-discharge cycle occurs when the charge is maintained between 40% and 80%. In contrast, lead-acid batteries last the longest only when discharged less than 5%.

Although Li-ion technology appears to have every advantage over other battery technology, Li-ion technology is restricted by a number of limitations. Extensive investment and research are currently aimed at correcting serious limitations to the use of Li-ion technology in heavy equipment applications. As a result, a variety of Li-ion chemistries are now competing for widespread use, each with unique advantages and disadvantages.

One disadvantage of current Li-ion battery technology is cost. Li-ion batteries currently cost eight times more than conventional lead-acid batteries for each kilowatt of power produced per hour. However, continuous innovation and increasing production are steadily dropping the price differential.

Chemical stability of Li-ion batteries is also a concern. High temperatures destroy some batteries, and they are known to overheat and even catch fire when overcharged or damaged. Complete discharge ruins other Li-ion batteries. The highly reactive chemistry of the Li-ion cell requires special safety precautions to prevent physical or electrical abuse of the battery. To maintain the cells within design operating limits, a microprocessor-controlled battery management system prevents damage and extends the life cycle of Li-ion batteries. Electronic controls add to production costs.

Valve-Regulated Lead-Acid (VRLA) Batteries

As mentioned, valve-regulated lead-acid (VRLA) batteries are sealed lead-acid batteries that do not have a liquid electrolyte and do not require the addition of water. This design has numerous advantages. Plate and electrolyte technology used in VRLAs result in lower self-discharge rates because VRLAs typically lose only 1–3% of their charge per month. This compares to lead antimony grid batteries having a self-discharge rate of 2–10% per week and with 1–5% per month for batteries using lead calcium grids.

Because VRLA batteries are completely sealed, they can be installed in any position without leaking—even under water. Sealing the battery eliminates the need to replenish the electrolyte or to check specific gravity. Battery state of charge is determined through voltage checks. Listed here are other advantages of VRLA batteries:

- No required specific gravity readings or adjustments
- No need to add distilled water
- No acid or lead to deal with in wash water
- No cable corrosion
- No tray corrosion
- No corrosive gas in battery compartment to damage electronics
- The longest service life of all battery types
- The highest cranking amps, even at low temperature
- The fastest recharge possible
- The highest vibration resistance
- 400 full cycles (80% DOD)
- Triple the life of traditional lead-acid batteries

The two common types of VRLA battery are absorbed glass mat (AGM) and gel. Additionally, a spiral cell battery, which is a variation of AGM technology, has actually become the more recognizable of the AGM-type batteries. We discuss each of these VRLA batteries in the following sections.

Absorbed Glass Mat (AGM) Batteries

Absorbed glass mat (AGM) batteries, as **FIGURE 12-25** illustrates, feature a unique and highly absorbent, thin glass fiber plate separator that absorbs the electrolyte like a sponge. The fiberglass-like plate separator, or mat, material gives the battery its AGM name. These batteries eliminate water loss through a process called oxygen recombination. No vents are used. Instead, the battery case is pressurized constantly to between 1 and 4 psi (6.9–27.6 kPa). Because of the special properties of the glass mat, pressurizing the battery causes 99%+ of the hydrogen and oxygen gases to recombine back into water when recharging. A piece of foil in place of a traditional vent cap allows the battery gases to vent only under severe conditions such as during overcharging when voltage is greater than 15 volts. If venting occurs, the battery is likely damaged, and the cell will dry out like any other cell. Charging above 2.7 volts per cell, the battery is severely damaged.

FIGURE 12-25 Construction details of a flooded absorbed glass mat (AGM) battery.

Advantages to AGM Batteries

AGM batteries have several advantages. Cell design places plates and separator mats closer together, which lowers the battery's internal resistance. A more efficient and faster chemical reaction between battery electrolyte and the plates can take place using the unique boron-silicate glass mat separator plate. Lower resistance and faster reactions means AGM batteries can charge at up to five times the rate of conventional lead-acid batteries. AGM cells produce slightly more voltage: 12.80–13.0 volts open-circuit voltage compared to 12.65 for conventional flooded lead-acid batteries. As a result, AGMs deliver more amperage at higher voltage when cranking. **TABLE 12-4** compares the state of charge and open-circuit voltage of flooded, gel, and AGM batteries.

Glass mat plate separators used in AGMs absorb mechanical shock better than other batteries. The vibration-resistant battery can therefore be used in operating conditions where other battery plates would quickly be destroyed. In one study, a fleet compared 68 trucks with conventional flooded batteries to 69 trucks with AGM batteries. Thirty-four months later, 113 of the flooded batteries had been replaced compared to eight of the AGM designs.

Service Precautions with AGM Batteries

AGM cells are extremely sensitive to damage from overcharging and require chargers that limit charging voltage to between

TABLE 12-4 State of Charge Versus Open Circuit Voltage

Charge	Open Circuit Voltage		
	Flooded	Gel	AGM
100%	12.65	12.85	12.80
75%	12.40	12.65	12.60
50%	12.20	12.35	12.30
25%	12.00	12.00	12.00
0%	11.80	11.80	11.80

FIGURE 12-26 Technicians should use only microprocessor-controlled, or “smart,” chargers to charge AGM batteries.

14.4 and 14.6 volts maximum at 68°F (20°C). Using conventional shop taper chargers, which can charge at up to 18 volts, will destroy an AGM battery. Sustained charging at 15 volts also causes the battery to overheat and gas excessively due to electrolysis. Instead, technicians should use a smart charger, such as the one in **FIGURE 12-26**. A **smart charger** is a battery charger with an internal microcontroller that regulates charging rates and times. It is an intelligent, temperature-compensated charger with an “AGM” setting. Because cell voltage is slightly higher for AGM batteries, a vehicle's charging system voltage may need adjustment to keep it in range between 13.8 and 14.4 volts maximum at 68°F (20°C) for optimum performance and service life. Voltage-regulator settings on some vehicles are too high for AGM batteries and may require adjustment. The higher open-circuit voltage also means that to prevent unequal charging and shortened battery life, operators cannot mix AGM batteries with other battery types. Without access to the electrolyte, AGM state of charge can only be determined by measuring battery voltage.

The depth of discharge also affects the life cycle of batteries. In general, the deeper the discharge between charges, the shorter the life cycle of batteries. **TABLE 12-5** compares the depth of discharge against the number of charge/discharge cycles that one can expect from different battery chemistry types.

SAFETY TIP

AGM batteries are very sensitive to overcharging, as they will gas excessively and burst cell vents. Intelligent chargers that limit maximum charging voltage to 14.6 volts are required. Technicians should not use traditional taper chargers (used by most shops) that have an adjustable charging amperage setting to charge AGM batteries because taper chargers increase charging amperage to batteries by raising voltage to over 15 volts—and as much as 18 volts in some conditions.

Spiral Cell Optima Batteries

In the late 1980s, AGM battery technology advanced further with the introduction of spiral-wound plate technology.

TABLE 12-5 Comparison of Depth of Discharge Cycle to Battery Life for Different Battery Chemistries

Depth of Discharge	Gel: Cycle Life	AGM: Cycle Life	Flooded Lead-acid: Cycle Life	Li-ion	NiMH
100%	450	200	30–150	Potentially ruined/ damaged with some Li-ion chemistries	500–3,000 (demonstrated only)
80%	600	250			
50%	1,000	500	500	2,000	
25%	2,100	1,200			
10%	5,700	3,200	2,000	Millions +	300,000+ (demonstrated only)

FIGURE 12-27 A typical spiral-wound cell battery. Note the cylindrical cells.

FIGURE 12-27 shows a typical spiral-wound cell battery. **Spiral-wound cell batteries** are AGM batteries in every way except that the electrodes for each cell are not made of rectangular plates. Instead, two long, thin lead plates—the positive and negative electrodes—are coiled into a tight spiral cell with an absorbent microglass mat placed between the plates absorbing the electrolytes, as **FIGURE 12-28** illustrates. Replacing multiple plates with two coiled electrodes reduces internal battery resistance even further, thus enabling higher charging absorption rates for faster charging and higher discharge rates. These batteries also use higher internal gas pressures than other AGM batteries.

Manufacturers produce spiral cell batteries in three categories, designated by the color of the battery’s top cover:

- Red top—a 12-volt SLI battery
- Blue top—a deep cycle battery
- Yellow top—a combination deep cycle and SLI or leisure battery

Gel Cell

Just as battery plate and grid materials technologies have advanced to allow more powerful, lighter, and longer-lasting lead-acid batteries, electrolyte technology has also evolved. In

FIGURE 12-28 Spiral cell batteries are the more recognizable type of AGM battery technology.

the mid-1960s, the industry introduced spill-proof batteries using gel cells. **Gel cell batteries** are created by adding silica powder to the electrolyte, which turns the liquid into the consistency of petroleum jelly, hence the name “gel cells.” A fully charged gel cell battery has an open-circuit voltage of at least 12.85 volts and, like AGM cells, gel batteries are sensitive to overcharging and can be ruined by overcharging.

Ultracapacitors

Compared to more traditional capacitors, **ultracapacitors** are a new generation of high-capacity and high-energy density capacitors. Capacitors are electrical devices well known for their ability to store short bursts of electrical energy temporarily. For example, capacitors suppress and smooth voltage fluctuations, or ripple, from alternators. Capacitors also suppress radio static when connected across the power line-in. Ultracapacitors can supply large bursts of energy and quickly recharge themselves, which make them ideal for use in modern vehicles. Ultracapacitors are particularly advantageous in situations requiring regenerative braking and in frequent stop–start systems, such as in electric and hybrid vehicles.

Ultracapacitors have a very low internal resistance when compared to lead-acid batteries. Consequently, ultracapacitors deliver and absorb high-energy currents much more readily. In hybrid vehicles, using regenerative braking applications, typical batteries are slow to absorb a charge, thus limiting the maximum recovery of energy. Ultracapacitors do not have this problem and quickly recharge when depleted. This also makes them ideal for plug-in hybrid technology because they allow vehicles to recharge in seconds—not hours! Furthermore, unlike other battery technologies, continuous charge and discharge cycles do not wear out ultracapacitors. Whereas other battery technologies can be cycled between 200 and several thousand times, ultracapacitors can be cycled literally millions of times!

An ultracapacitor is constructed using two electrodes (plates), an electrolyte, and a separator plate, as **FIGURE 12-29A** illustrates. The dielectric material is double layered—not single as in conventional capacitors—and is made from a porous carbon. Although the construction features are similar to those of a galvanic-type battery cell, the method by which it stores

electrical energy is different. Ultracapacitors store electrical energy within electrostatic fields (electrostatically) and do not produce electricity through electrochemical reactions. Like any capacitor, the main factors that determine how much electrical energy an ultracapacitor can store are as follows:

- Plate/electrode surface area—the greater the plate area, the higher the capacity.
- Distance between the plates—the closer the plates are, the higher the capacity.
- Electrical properties of the dielectric insulating layer separating the electrodes—some materials have better storage properties within capacitors than others.

A popular ultracapacitor type battery is the Maxwell ESM Ultra[®] series **FIGURE 12-29B**. Having the same dimensions as a group 31 battery, it can also produce 1800 CCA for 3 seconds and is unaffected by the cold. Three terminals are used: two are for charging the battery, and a third connects directly to the starter motor. An internal battery control module regulates the charging rate to each cell and performs diagnostic tests. Ultracapacitors are currently used to assist batteries for the first 1.5 seconds during cranking, where they can supply an additional 2,000 amps of current to supplement the starter batteries, as **FIGURE 12-30** illustrates. That supplement increases starter torque and speed when cranking amperage is highest during the initial starter engagement.

FIGURE 12-29 A. Construction of an ultracapacitor. **B.** Maxwell ESM Ultra series battery.

► Battery Management Systems

K12008

Battery failure is a costly service issue for heavy equipment. Weak batteries can lead to premature failure of starting and charging system components and loss of service caused by no-start conditions. The severe operating conditions and use of multiple batteries in many heavy equipment vehicles contribute to shortened battery life. Various electrical devices and systems that manage battery performance help minimize the expense and disruption due to battery failures. **Battery management systems (BMSs)** perform the following functions:

- Protect the cells or the battery from damage
- Prolong the life of the battery
- Maintain the battery in a state of charge to perform the work for which it is specified

The development of commercial hybrid-vehicle applications places more demands on batteries and requires sophisticated battery management systems for sensitive battery technology. Components of the battery management system include battery isolators, low-voltage disconnects, battery balancers and equalizers, and battery monitors. We discuss each of these components in the following sections.

Battery Isolators

Many heavy equipment vehicles use multiple batteries that we can separate according to function. For example, consider a

FIGURE 12-30 This ultracapacitor supplements the cranking current for a 24-volt battery, which reduces starting time.

vehicle with one battery bank of starting, lighting, and ignition (SLI) batteries for the starting and main vehicle operating system and another set of batteries for auxiliary deep cycle batteries for accessories or systems that operate after the engine shuts down. Permanently connecting all the battery banks in parallel could cause the SLI battery to become discharged if a continual electrical load is placed on the auxiliary deep cycle batteries for extended periods. This would prevent the vehicle from starting.

Battery isolator systems, or **split charge relays**, as **FIGURE 12-31** illustrates, enable the vehicle charging system to charge the auxiliary battery but electrically separate the auxiliary battery from the starting circuit when the engine shuts down. Separation of the main starting and auxiliary batteries can take place automatically during charging and discharging. Battery isolation systems range from simple, isolating solenoids or relays, to complex battery management systems that monitor charge rates and voltages for both the SLI and auxiliary batteries.

FIGURE 12-31 An isolator circuit ensures that auxiliary loads do not drain the chassis battery used for starting when the charging system is not operating. When the engine starts, the alternator charges both batteries, with the control module switching the isolator relay on and off under the appropriate conditions.

Low-Voltage Disconnect

Low-voltage disconnects (LVDs) monitor battery voltage and disconnect noncritical electrical loads when the battery voltage level falls below a preset threshold value. LVD devices preserve battery current to a level adequate to start the vehicle's engine when key-off loads or other parasitic draws are draining the battery. LVD devices then reconnect the electrical loads when the battery level is restored to a high enough voltage—for example, when the alternator begins charging above 12.6 volts. No intervention is required by the vehicle operator to protect the batteries, as the LVD automatically disconnects and reconnects the load. An audible warning typically alerts the operator before a disconnect event occurs, which is generally between 12.0 and 12.2 volts. LVDs can be integrated with the vehicle's power distribution system and progressively shed loads as battery voltage drops.

Battery Balancers and Equalizers

Higher cranking amperage and greater electrical loads in heavy-duty equipment require two or more batteries connected either in series for 24-volt electrical systems, or in parallel in 12-volt systems. Charging and discharging resistance changes with battery use and the electrical distance from the alternator. For example, longer battery cables and more electrical connections are almost unavoidable in many vehicles.

This means one or more batteries in a bank get undercharged, which in turn leads to progressive plate sulfation. Sulfation, in turn, increases battery resistance, causing the battery to become weaker (**FIGURE 12-32**).

Balancers (sometimes called **battery equalizers**), as **FIGURE 12-33** illustrates, attempt to adjust battery voltage to compensate for unequal charges in multiple batteries. Equalizers are found in many commercial applications using 24-volt charging systems, including off-highway equipment.

In multiple battery configurations, whether connected in series or in parallel, batteries eventually charge and discharge unevenly, shortening battery life. For example, you may often discover that while testing two 12-volt batteries connected in parallel, one battery becomes completely dead while the other stays in good condition. When testing three batteries, one will be good, another fair, and the third defective. The defective battery is always the farthest from the alternator in terms of electrical distance.

There are two methods of correcting this common condition of unequal charge and discharge rates. One is to regularly rotate the batteries and exchange their positions in the configuration. Another method is to use a battery equalizer. Also, remember to check the equipment manufacturer's recommendation for connecting battery cables. Properly connecting cables is one way to minimize the charge and

FIGURE 12-32 Batteries can develop unequal resistances with use.

FIGURE 12-33 The equalizer controls the charging rate of two 12-volt batteries as well as evenly balances the current drawn from each.

discharge imbalances between batteries. Various configurations of charge equalizers enable the following:

- Charging 12-volt batteries from a 24-volt charging system
- Charging 24-volt batteries from a 12-volt charging system
- Charging series-connected 12-volt batteries at 24 volts and providing a 12-volt output for 12-volt chassis electrical loads
- Balanced battery charging of 12-volt batteries from 24 volts to within a difference of 0.1 volt
- Balanced draining of batteries to supply a 12-volt load so that each battery is depleted to within a difference of 0.1 volt

A common configuration has 12-volt batteries connected to the equalizer that interfaces the batteries with the 24-volt alternators, as **FIGURE 12-34** illustrates. The equalizer senses battery voltage and drives a higher charge rate into weaker batteries and less current into stronger batteries. The voltage balance and charge acceptance rate of each battery is kept to within 0.1 volt under light loads and within 0.5 volt at full loads. When the voltage of battery A is higher than that of battery B, the battery equalizer switches to standby mode. This means no power transfers from its 24-volt alternator input to its 12-volt output. If a 12-volt load is present, and battery A's voltage decreases to just below the voltage of battery B, the battery equalizer activates and transfers sufficient current from battery B to battery A, satisfying the load and maintaining an equal voltage and charge in both batteries.

More complex systems, like that in **FIGURE 12-35**, can have both battery isolation and battery equalization across multiple banks. For example, chassis batteries are isolated from each other when the alternator is not charging, but are connected together so both banks charge when the alternator is charging, and there is battery equalization for each bank.

Charge equalization is critical for series-connected battery cells in hybrid-vehicle applications. The higher voltage in

FIGURE 12-34 Battery equalizer used to ensure batteries within the bank remain charged with 12- and 24-volt mixed loads.

hybrid-drive systems requires very long series strings of batteries pushing battery performance to extremes. Without battery management systems incorporating charge equalization, battery banks would quickly fail.

Battery Monitors

Battery monitors in hybrid heavy equipment vehicles collect battery data for display to the operator and service technician. The data the monitors typically collect include the following:

- Temperature of each battery or pack
- Voltage of the pack
- Rate of charge or discharge

Hybrid Battery Management Systems

Hybrid-drive battery management is much more demanding than the previously described battery management devices. Batteries in these applications work in a demanding and harsh environment because of rapidly changing charging and discharging conditions, such as when the vehicle accelerates using electric motors and charges during regenerative braking. Li-ion and NiMH batteries best charge to between 40% and 70% of full capacity to allow absorption of current generated during braking and to extend their lifecycle. An on-board battery

FIGURE 12-35 Schematic diagram of a battery equalizer combined with a battery isolator. The chassis system provides current to supply the starting motor batteries.

management system, like that in **FIGURE 12-36**, performs some, but not necessarily all, of the following functions:

- Monitoring the state of charge (SOC) of the battery and battery cells that compose the battery banks; this function is often the equivalent of a fuel gauge distance-to-empty reading
- Maintaining the state of charge (SOC) of all the cells with both voltage and amperage protection against overcharging and undercharge conditions
- Providing service and diagnostic information on the condition of the batteries and cells; this includes recording battery service and diagnostic data (battery voltage readings, temperature, hours, faults, out of tolerance conditions)
- Providing information for driver displays and alarms
- Providing an emergency protection mechanism in the event of damage, uncontrolled overheating, or other abuse condition
- Isolating the batteries or cells
- Charge equalization within the battery bank
- Adjusting the battery SOC to enable regenerative braking charges to be absorbed without overcharging the battery
- Communicating with the on-board vehicle network to receive information and instructions from other electronic vehicle-control units and responding to changes in the vehicle operating mode
- Calculating the optimum charging rate to each battery and/or cell
- Enabling adaptive strategies or emergency “limp home” mode in case of battery failure
- Providing reverse polarity protection
- Controlling temperature-dependent charging; some batteries can be damaged by charging when temperatures are lower than 32°F (0°C) or above 100°F (45°C)
- Providing discharge current protection to prevent damage to cell due to short circuits
- Providing depth of discharge cutoff

► Battery Servicing, Repair, and Replacement

AI 2002

Battery maintenance is often overlooked, and often the cause of a dead machine is the result of a lack of maintenance for the battery system. Simple things like checking electrolyte level, keeping the battery clean and secure, and checking and cleaning connections help get full life from a battery. If a large fleet of machines is able to get an extra season out of the battery in each machine because of a little extra maintenance, it could add up to thousands of dollars saved without including the cost of

FIGURE 12-36 Diagram of the operation of a battery management system used in a hybrid-vehicle chassis.

machine downtime. There is also a huge environmental benefit to having batteries last as long as possible.

Because of the constant chemical-to-electrical change (self-discharge, discharge, or charge) and the harsh environment a battery must withstand in a machine (vibration, dirt, temperature extremes), the battery has a limited life. Proper care (cleaning, adding water, and charging) will extend the life of the battery.

Batteries should be the starting point when diagnosing complaints such as hard starting, slow cranking, or no-start complaints (**FIGURE 12-37**). Battery testing is also indicated when lights dim when an engine idles or when other electrical problems occur. Battery testing is also recommended whenever an alternator is replaced. Technicians use a variety of instruments and tools to evaluate the condition of vehicle batteries, and they use a number of procedures to service batteries during maintenance checks. This section covers these techniques.

Traditional comprehensive maintenance and testing of batteries include the following evaluation methods:

- Visual inspection, cleaning, filling, and battery replacement
- Checking that batteries are covered and secured in place
- Checking that cables ends are secure
- Checking that cables are not frayed or broken
- SOC testing using a voltmeter
- Cell voltage checks
- Load or capacity testing

FIGURE 12-37 Regular battery maintenance reduces downtime.

- Conductance or impedance testing
- Charging batteries
- Jump-starting vehicles
- Measuring parasitic draw

Technicians should evaluate batteries visually first before proceeding with any other significant tests. Visual checks include checking the electrolyte level, if possible. Most batteries today are sealed, or low- or no-maintenance type, which prevents this procedure.

Another basic maintenance task is to make sure the exterior case is dry and free of dirt. Dirt on top of the battery can actually cause premature self-discharge of the battery as current “leaks” across the path of dirt or grime. Grime and vapors from a battery can become conductive and drain the battery over time. To tell whether the surface of the battery is leaking current, use a digital volt-ohmmeter (DVOM), like the one in **FIGURE 12-38**, set to “Volts” to measure the voltage on the surface of the top of the battery. Do this by placing the black lead on the negative battery post and rubbing the red lead around the top of the battery, measuring the voltage present there. Any voltage exceeding 0.5 volt means you should wash down the battery with water. Do not use mixtures of diluted ammonia or baking soda, as they can enter the battery cells and contaminate electrolyte.

Terminals should be covered or protected to prevent corrosion, which eventually causes excessive resistance. Secure batteries against vibration, which can damage plate material, by inspecting machines’ battery hold-downs regularly. Keep cable ends tight, and secure the cables so they do not rub against part of the machine and expose the wire. Machines have caught fire because of a battery or cable being loose and shorting out.

FIGURE 12-39 shows a properly secured battery.

FIGURE 12-38 Measure voltage between points on the surface of the battery top to determine if there is any leakage current.

FIGURE 12-39 A properly secured battery.

Batteries should be fully charged to perform properly and to prolong their service life. A weakened battery causes the alternator to work harder charging batteries and shortens the alternator’s life. Lower current level available to the starter leads to low-voltage burnout of the starter too. We cover state of charge in detail in the section Testing Battery State of Charge and Specific Gravity.

The section Battery Inspecting, Testing, and Maintenance covers several tests the tech can use to determine battery service life and identify reasons for battery failure. Load or capacity tests determine the ability of a battery to deliver cranking amperage, which we discuss in detail in the section Testing Battery Capacity. Conductance testing, or impedance testing, has replaced this method for evaluating battery capacity, which we cover in the section Testing Battery Conductance. Technicians do not perform testing for sulfation as part of a regular battery evaluation, but only to validate a diagnosis of sulfation. We discuss this procedure in the section Performing a Sulfation (3-Minute Charge) Test.

Parasitic draw testing and case drain or leakage testing are other means to detect conditions that cause batteries to lose their charge. A parasitic drain of battery current should be no more than 0.5 amp of current. Placing an inductive ammeter battery cable with all vehicle accessories off easily measures and detects excessive draw. Wet and dirty batteries leak voltage too. Placing one voltmeter lead on a battery post and the other lead on the case identifies voltage leaks exceeding 0.5 volt. Technicians should clean and dry battery cases to remove electrically conductive grime from the case. We discuss parasitic draw in greater detail in the section Measuring Parasitic Draw.

► TECHNICIAN TIP

To prevent corrosion and resistance from developing at battery connections, you should apply treatments specifically designed to coat battery terminals. These treatments are not electrically conductive and do not attack cable insulating materials. Many other types of grease, such as chassis grease, are electrically conductive and lead to battery self-discharge and even corrosion of battery terminals.

► Battery Service Precautions

K12009, A12001

The Prevent Blindness America organization recently reported that nearly 2,000 people in the United States suffer eye injuries every day. For this reason, safety should be the first priority when working around and servicing batteries. Batteries are dangerous for a couple of reasons. First, electrolyte inside lead-acid batteries is corrosive. Acid on skin, in eyes, on clothing, or on paint will burn, causing bodily harm and vehicle damage. Also, an explosive gas mixture consisting of hydrogen and oxygen is produced during charging and discharging of the battery. Follow these precautions to reduce the risk when working with batteries:

- Always wear protective clothing such as rubber gloves and goggles or full-face shields when handling batteries. When

handling a battery or checking electrolyte levels, wear a rubber apron to protect clothing from splashed battery acid. If acid contacts your skin or eyes, flush with water immediately.

- Never wear any conductive jewelry (neck chains, watches, or rings) when working on or near batteries, as they may provide an accidental short-circuit path for high currents.
- Do not smoke, weld, or grind metal near batteries because sparks may ignite the explosive gas mixture.
- Never create a low-resistance connection or short across the battery terminals.
- Never disconnect a battery charger, jumper cables, or power booster from a battery when charging or jump-starting. Sparks will occur when disconnected and can result in battery explosions. Shut the power booster off. Disconnect the chassis ground clamp that is away from the battery first. Connect the ground clamp last when boosting.
- Charge batteries in a well-ventilated area. Always remove the negative or ground terminal first when disconnecting battery cables, because this procedure reduces the possibility of a wrench creating a short circuit between any positive voltage wiring and the chassis ground.
- Tighten all battery cable connections to the battery terminals properly. Loose connections are resistive and may cause sparks.
- Never set a wrench or other tool on a battery, as doing so can cause short battery terminals, leading to gassing, overheating, and an explosion in an alarmingly short period.

► TECHNICIAN TIP

Always connect and disconnect the main battery ground first. If there are other ground cables connected to the battery for the engine and other electronic control modules, connect these grounds last. When additional grounds are either connected or disconnected and you do not connect the main battery ground, voltage spikes could occur and may damage electronic control modules.

SAFETY TIP

Never allow a spark or flame around a battery, and never try to jump-start a frozen, faulty, or open-circuit battery; doing so could cause the battery to explode, causing injury.

► Causes of Battery Failure

K12010

According to several studies, batteries cause 52% of vehicle breakdowns or failures to provide service. Battery failures are by far the leading cause for service breakdowns, with tires being the next most common (15%), followed by engines (8%). The two most common complaints concerning batteries are that either they do not charge or do not hold a charge. Batteries may suddenly fail through the loss of a cell or because of open

circuits within the internal connections. Plate deterioration through the gradual loss of capacity also causes batteries to fail slowly over time.

Sulfation

According to a study, of all lead-acid batteries customers returned to the manufacturer under warranty, close to half were found to have no defect. Of those found defective, sulfation caused close to 80%. You can observe sulfation when a white-colored substance coats and swells, as **FIGURE 12-40** shows. It occurs when batteries are subjected to prolonged undercharge conditions. During normal use, soft sulfate crystals form and dissipate as part of the normal charge and discharge cycle. During periods of prolonged undercharge, the sulfate converts to hard crystals and deposits on the negative plates. During subsequent charging, the hardened sulfate cannot be driven from the plate and reduces the active area of plate material. Sulfation also increases the internal resistance of a battery. This means higher charging voltage is needed to regenerate active plate material when charging. Pulse-type battery chargers have a setting for potentially reconditioning batteries that may have been sitting for periods of time in an undercharged state. Listed here are some common reasons for sulfation:

1. *Leaving batteries too long in a state of discharge:* Soft sulfation occurring during normal discharge turns to hard sulfate crystals over time. Batteries should be recharged as soon as possible after discharging. Key-off loads, also called parasitic drains, contribute to sulfation caused by prolonged discharge.
2. *Undercharging a battery:* High resistance at battery connections, particularly in batteries connected in series or parallel, leads to undercharging of cells. Incorrect charging system voltage can also cause undercharging.
3. *High ambient temperatures:* Temperatures in excess of 100°F (39°C) speed up chemical activity inside a battery, accelerating the self-discharge of a battery. Experts calculate that a new, fully charged, flooded battery would most likely not start an engine in as little as 30 days if exposed continuously to 110°F (47°C). Significantly higher rates of battery failures occur in warm regions of North America than in cold areas. To minimize self-discharge, store batteries in cool, dry places.
4. *Low electrolyte level:* Battery plates exposed to air dry out and prevent transfer of sulfate from the plate material back into electrolyte during charging. Adding acid to a battery does not recover a dead battery. Instead, it increases the concentration of sulfate in the battery.

FIGURE 12-40 Sulfate on the top of the plates of a lead-acid battery.

Performing a Sulfation (3-Minute Charge) Test

Use a 3-minute battery charge test to indicate sulfation. Perform this test as part of a regular battery evaluation, but only to validate a diagnosis of sulfation. This battery test requires you to charge the battery at 30–40 amps for 3 minutes, while measuring the battery voltage with the charger on. If the voltage rises above 15.5 volts, the battery is excessively resistive and is likely sulfated.

Vibration

Excessive vibration can cause open circuits in the internal battery connections; it can also produce “shed,” or loose plate material, which settles to the bottom of the battery case. Shedding reduces the plate surface area and therefore reduces capacity. **Shedding** may also produce short circuits between the bottom of positive and negative plates.

Electrolyte Level and Condition

Low electrolyte level exposes the plates to air, preventing the transfer of sulfate from the plate material back into the electrolyte during charging. It is critical to maintain the correct acid–water mix of electrolyte. If electrolyte level is lost through evaporation, then add distilled water. If electrolyte is lost due to spillage, then top up the battery with electrolyte. Examine the electrolyte to detect damaged plates and grids. Gray or dirty electrolyte in any cell renders a battery defective. Although voltage and electrolyte readings may be satisfactory, contaminants, even in one cell, cause the battery to self-discharge quickly. Series connections between cells cause even one dead or defective cell to discharge all other cells in the battery. Check electrolyte condition at the same time you evaluate specific gravity.

Grid Corrosion

Grid corrosion, like that in **FIGURE 12-41**, takes place primarily in the positive grid and is accelerated by overcharging and high temperatures. When corrosion takes place, grid resistance increases during charging and discharging. Grids are the foundation and the electrical conducting layer for the battery plate.

FIGURE 12-41 Corroded grids increase battery resistance, making the battery harder to charge and causing low supply voltage when cranking.

Although manufacturers alloy grids with antimony, calcium, or sometimes barium to minimize the corrosive effects of the electrolyte, grids do disintegrate. The mudlike lead paste attached to grids also falls apart when grids corrode.

► Battery Inspecting, Testing, and Maintenance

KI2011; SI2001, SI2002, SI2003, SI2004

As noted earlier, batteries last longer if they are properly maintained. In fact, one of the most common causes of vehicle no-starts is dirty or corroded battery cables. Inspecting, cleaning, and filling (if not maintenance free) are common tasks that the technician should perform every 6 months to 1 year on top-post batteries, and 1–2 years on side-post batteries. During periodic maintenance, check batteries for proper ventilation. All slide mechanisms on battery trays should work properly. Inspect battery cables for rubbing or binding. Battery terminals should be tight and show no evidence of overheating. Always coat battery terminals with a dielectric sealer to prevent corrosion. Evaluate batteries visually first before proceeding with any other significant tests. Visual checks include these:

- Cracks
- Bulges—indicate batteries have either overheated or been frozen
- Cable connections—connections should be clean, tight, acid resistant, and show no signs of heat damage
- Battery hold-downs—loose or missing hold-downs cause plate shedding
- Dirty case—causes current to leak out of batteries
- Leaks
- Electrolyte level—level should be above the plates
- Electrolyte appearance—liquid should be clear; a brownish color may indicate damaged plates or contaminated electrolyte

To inspect, clean, fill, or replace the battery, battery cables, clamps, connectors, and hold-downs, follow the guidelines in **SKILL DRILL 12-1**.

Testing Battery State of Charge and Specific Gravity

Although the capacitance test is the industry standard to evaluate battery condition, technicians may still use other tests. One of those tests is the state of charge (SOC) test. As the term suggests, **state of charge** refers to the charge condition of the battery and is expressed as a percentage of a fully charged battery. In other words, SOC testing tells you how charged or discharged a battery is, not how much capacity it has.

A fully charged battery should have an open-circuit voltage of 12.65 volts. If the battery has been recently charged, a light load applied to the battery for a minute removes a surface charge. Open-circuit voltage is consequently affected by the battery specific gravity. About 1/12-volt change occurs for every 10°F below 80°F. **TABLE 12-6** shows SOC as indicated by specific gravity and voltage reading.

SKILL DRILL 12-1 Inspecting, Cleaning, Filling, or Replacing the Battery, Battery Cables, Clamps, Connectors, Hold-Downs, and Battery Boxes

1. Always remove the cable clamp from the negative terminal first. Then remove the positive terminal clamp. While they are disconnected, bend the cables back or, if necessary, tie them out of the way so that they cannot fall back and touch the battery terminals accidentally.
2. Remove the battery hold-downs or other hardware securing the battery. Depending on the type of vehicle, you will need to unbolt, unscrew, or unclip the restraint and move it away from the battery.
3. Keeping it upright, remove the battery from its tray and place it on a clean, level work surface. Visually inspect the battery for damage, cracks, bulges, loose or leaking posts, and so on. If you find any, you need to replace the battery.
4. Measure the voltage on the top of the battery with a DVOM. Place the black lead on the negative post and move the red lead

across the top of the battery until you find the highest reading. The higher the voltage reading, the larger the potential drain.

5. Check the electrolyte level and its appearance.
6. Carefully clean the case of the battery, hold-downs, and battery tray and box either by (a) washing them or (b) wiping them down with damp paper towels if the battery and tray are not very dirty. It is best to wear rubber gloves while doing this, in case any corrosive electrolyte has leaked from the battery. Safely dispose of the paper towels.
7. Clean the battery posts or screw terminals with a battery terminal tool. On lead posts and terminals, the preferred tool is a scraper style, as it produces smooth surfaces that are more airtight when clamped together. Do not use the wire brush-style battery terminal tool, which leaves rougher surfaces that are more likely to corrode.
8. Clean the cable terminals with the same battery terminal tool or wire brush. Examine the battery cables for fraying or corrosion. If the damage looks extensive, replace the cables and terminals.
9. Reinstall the cleaned and serviced battery. Reinstall the hold-downs and make sure they hold the battery securely in position. If you need to install a new battery, be sure to compare the outside dimensions as well as the type of terminals and their locations prior to installation. These must meet the original manufacturer's specifications.
10. Reconnect the positive battery terminal and tighten it in place. Once the positive terminal is finished, reconnect the negative terminal and tighten it.
11. Coat the terminal connections with anticorrosive paste or spray to keep oxygen from the terminal connections. Verify that you have a good electrical connection by starting the vehicle.

TABLE 12-6 State of Charge as Indicated by Specific Gravity and Voltage Reading

Open Circuit Voltage	Specific Gravity	Percentage of Charge
12.65 or greater	1.265 (minimum)	100%
12.45	1.225	75%
12.24	1.190	50%
12.06	1.155	25%
11.89	1.120	0%

Voltage reading can also identify defective cells. Using a multimeter, place one meter lead on either terminal of the battery, and dip the other lead into battery electrolyte (if accessible). The meter should record a change of 2.1 volts for each cell when moving across the battery.

Measuring the density of electrolyte in each cell using either a bulb-type hydrometer or refractometer is the best way to evaluate the SOC. The specific gravity (SG) of

electrolyte indicates the state cell charge. Cells should not have wide variations. If the SG reading between the highest and lowest cell is more than 0.050 point, the battery is defective. For example, if the highest SG is 1.265 points in one cell and only 1.210 in the lowest, the battery is scrap. **FIGURE 12-42A** and **FIGURE 12-42B** show two different tools technicians use to measure battery specific gravity. **FIGURE 12-42B** shows a refractometer.

Unlike the reading from a refractometer, you must correct the hydrometer's reading for electrolyte temperature. The density of battery electrolyte changes with temperature and 1.265 is only the density of electrolyte at 80°F (27°C). To correct for temperature effects on specific gravity, add or subtract 4 points to the reading either above or below 80°F (27°C) for every 10°F (6°C) temperature change. (For example, add 0.004 for temperatures at 70°F [21°C].) Because the hydrometer draws electrolyte into it to raise a float, the electrolyte level must be at least slightly above the top of the plates. If it is not, then you need to add distilled water and fully charge the battery. To perform a battery SOC test, follow the guidelines in

SKILL DRILL 12-2.

FIGURE 12-42 **A.** A hydrometer. **B.** A refractometer. You can use either to check the specific gravity of battery electrolyte in flooded cell batteries.

SKILL DRILL 12-2 Performing a State of Charge Test

1. If the battery is not a sealed unit, it has individual or combined removable caps on top. Remove them and look inside to check the level of the electrolyte. If the level is below the tops of the plates and their separators inside, add distilled water or water with a low mineral content until it covers them. Be careful not to overfill the cells; they could “boil” over when charging. If you add water, you need to charge the battery to ensure the newly added water mixes with the electrolyte before measuring the specific gravity.

2. Using a hydrometer designed for battery testing, draw some of the electrolyte into the tester, and look at the float inside it. A scale indicates the battery’s relative state of charge by measuring how high the float sits in relation to the fluid level. A very low overall reading (1.150 or below) indicates a low state of charge. A high overall reading (about 1.280) indicates a high state of charge. The reading from each cell should be the same. If the variation between the highest and lowest cell exceeds 0.050, the battery is defective, and you should replace it. Be sure to consult temperature correction tables if the battery electrolyte temperature is not at or around 80°F (27°C).

3. Using the refractometer, place one or two drops of electrolyte on the specimen window, and lower the cover plate. Make sure the liquid completely covers the specimen window. If not, add another drop of electrolyte:

- Look into the eyepiece with the refractometer under a bright light.
- Read the scale for battery acid. The point where the dark area meets the light area is the reading. Compare the readings with the values in step 2.

4. For open-circuit voltage testing with a DVOM, perform the following actions: (a) With the engine not running, select the “volts DC” position on your DVOM, and attach the probes to the battery terminals (red to positive, black to negative). (b) With all vehicle accessories switched off and the battery near 80°F (27°C), the voltage reading should be 12.65 volts if the battery is fully charged. This may be slightly lower at cooler temperatures.

► **TECHNICIAN TIP**

When performing an SOC test, keep these tips in mind:

- When filling a battery that is not fully charged, never fill it to the top of the full line, as charging the battery raises the electrolyte level.
- Be aware that small amounts of electrolyte in the hydrometer may leak out, potentially damaging and corroding parts and battery terminals.
- Do not inadvertently remove electrolyte from one cell or add it to another cell when testing; doing so causes incorrect readings.

Checking OCV (Open-Circuit Voltage)

Open-circuit voltage (OCV) is the difference of the electrical potential between the two terminals of a battery when the battery is disconnected from any circuit. Batteries should maintain an open-circuit voltage of 12.50 volts or greater. Use a voltmeter to check a battery’s OVC.

To determine the stabilized open-circuit voltage, you need to remove the surface charge on the battery if the machine has been run in the last 10 hours. (If the machine has not been run for the last 10 hours, this step is not necessary.) To remove the surface charge, turn on three or four work lights (or any light load) and leave them on for 3–5 minutes. You can now check the battery. Place the negative lead of a multimeter on the negative terminal leaving the battery system and the positive lead on the positive terminal leaving the battery system. See **TABLE 12-7** to compare OCV to percentage charged.

Use a load tester to simulate placing a heavy load on a battery. Then check the OCV during and after you apply the load. The battery should have an OCV of at least 12.4 VDC before doing this test. The proper method is to apply a load equal to half the batteries CCA for 15 seconds and read the OCV at the end of the load test. If the battery voltage drops below 9.6 V, recharge and retest the battery. If it fails again, replace the battery.

Testing Battery Conductance

Evaluating a battery’s condition using hydrometers, refractometers, and load testers provides reasonably accurate results if the technician uses the instruments correctly and the tech tests the battery under proper conditions. In the

field, however, batteries often need charging for hours before the tech can test them, and SOC testing is time consuming.

In cold weather, testing on equipment outside presents other problems too. In the last 15 years, several rapid-test battery testers have emerged that eliminate the need for SOC and discharge-type testing. Referred to collectively as conductance testers, this equipment performs a measurement of the amount of active plate surface area available for chemical reaction. Active plate surface, as measured by conductivity, is a reliable indication of a healthy battery, as it corresponds directly to battery capacity. Also referred to as impedance testing, the AC equivalent to resistance, battery plate conductance declines as the battery fails.

All manufacturers are now requiring the use of a conductance test instead of a high-amperage load test in order for the company to consider warranty coverage. A **conductance test** determines the battery’s ability to produce current. Many of the testers have integrated printers and, for the battery to be warranted, a printout of the test result has to accompany the battery return. Advantages of conductance testing are as follows:

- It does not require any battery discharge activity.
- It requires only minimal technician involvement, as the technician attaches only two clip-on connectors to the battery terminals during the test.
- It is fast—the tech can usually perform testing in less than 2 minutes.
- Low-frequency AC does not affect battery. Conductance testing does not prematurely age the battery.
- It is safe—it produces no heat or gassing.
- Technicians can repeat conductance testing immediately to verify the result.
- The technician can evaluate batteries in a state of discharge; some testers only require as little as 2 volts of battery voltage to qualify the battery
- All electrical standards testing organizations including Battery Council International (BCI) endorse the testing method.
- Printed read-outs can be supplied to the customer or to accompany warranty claims (**FIGURE 12-43**).

TABLE 12-7 OCV Compared to Percentage Charged

Item	Measurement	Specification
Stabilized open circuit 12.5 volts or more	Percent charged	100
Stabilized open circuit 12.4	Percent charged	75
Stabilized open circuit 12.2	Percent charged	50
Stabilized open circuit 12.0	Percent charged	25
Stabilized open circuit 11.7 or less	Percent charged	0

FIGURE 12-43 Printouts from a conductance tester.

The most common type of conductance tester works by applying an AC voltage of a known frequency and amplitude across the battery. A microprocessor inside the test unit interprets the battery's response to the signal. Conductance, or acceptance of the AC voltage, is measured by comparing the shape of the AC waveform exiting the battery to the waveform sent into the battery. The closer the waveforms match, the better the conductivity of the battery.

The most sophisticated testers today analyze lead-acid, Li-ion, and NiMH batteries, using a microprocessor containing algorithms that match waveforms from known battery configurations. These analyzers can identify not only the type and condition of a battery but also the manufacturer and other battery details. To conductance test a battery, follow the guidelines in **SKILL DRILL 12-3**.

► TECHNICIAN TIP

Never use steel bolts, nuts, washers, and so on on battery terminals when using conductance testers. Instead, only use the lead adapters supplied with the conductance tester. The materials and any coatings on other hardware interfere with the signals sent through the battery and affect the tester's accuracy. Conductance testing is best suited for SLI batteries and may not provide accurate results for deep cycle batteries using thicker plate.

Testing Battery Capacity

Traditionally, the load test evaluates a battery's capacity, but the test has become less popular due to the overwhelming advantages of conductance testing.

The **load test** determines the ability of a battery to deliver cranking amperage and is based on the battery CCA rating. For example, a 1000 CCA battery can deliver 1,000 amps at -18°C , or 0°F for 30 seconds, while maintaining a voltage of 7.2 volts. During a load test, only half the CCA rating is applied as an electrical load for 15 seconds.

A battery must be at least 75% charged to perform a capacity test, so the technician must first evaluate SOC before proceeding. A carbon pile is used to simulate the high-amperage electrical load on the battery. At the end of 15 seconds, after one-half the CCA rating has been applied, battery voltage must not fall below 9.6 volts. If it does, the battery is scrap. Because temperature affects battery voltage, 0.1 volt is subtracted from the failure threshold voltage level of 9.6 volts for every 10°F below 70°F .

Another way to think of a load test is that you are testing the battery's ability to produce the high starting current while maintaining enough voltage to operate the engine's electronic control systems.

If the battery fails the load test after you have properly qualified its SOC, the battery should be discarded. Do not attempt to recharge and reload the test after it has failed the first time. To load test a battery, follow the guidelines in **SKILL DRILL 12-4**.

► Charging Batteries

SI2005

Batteries go dead for a variety of reasons. Parasitic drains, self-discharge, or battery leakage are common reasons a battery may quickly lose its charge. A number of different chargers are available to recharge dead batteries, each with its own advantages and disadvantages.

Types of Battery Chargers

Differentiating between the types of battery chargers is useful for determining the best method for recharging a battery, given its condition and other operating variables. The most common types of chargers include constant-voltage chargers, constant-current chargers, taper-current chargers, pulsed chargers, and intelligent chargers.

- **Constant-voltage chargers**, like the one in Figure 12-43, are direct current (DC) power supplies that use a step-down

SKILL DRILL 12-3 Conductance Testing a Battery

1. Consult manufacturers' procedures and guidelines for the battery you are to test and for the tester you are using.
2. Isolate batteries if they are connected in a bank so that you can test them individually.
3. Identify the type of battery, size, and voltage for input into the test unit.
4. Save information and input as required into the test unit.
5. Run the test.
6. Analyze the results by comparing them to manufacturer specifications.
7. Print or record results of the battery test. Repeat steps if multiple batteries are to be tested.

SKILL DRILL 12-4 Load Testing a Battery

1. With the tester controls off and the load control in the off position, connect the tester leads to the battery. Observe the correct polarity, and be sure the leads fully contact the battery terminals.

2. Place the inductive amps clamp around either the black or the red tester cables in the correct orientation.
3. Verify that the battery's state of charge is more than 75% before beginning the test. Also measure the battery's temperature to make any correction to the cutoff voltage threshold.
4. If you are using an automatic load tester, enter the battery's CCA and select "Test" or "Start." If you are using a manual load tester, calculate the test load, which is half of the CCA. Turn the control knob or press the "Start" button.
5. Maintain calculated load of 1/2 the CCA rating for 15 seconds while watching the voltmeter. At the end of the 15-second test load, read the voltmeter; and immediately turn the control knob off. At room temperature, the voltage must be 9.6 volts or higher at the end of the 15-second load. If the battery is colder than room temperature, correct the battery failure threshold voltage against temperature. Close to 1/10 volt lower is allowed for every 10°F below 70°F. Using the results from the test, determine any necessary action.

transformer and a rectifier to convert AC voltage to DC voltage for charging. As the name suggests, output voltage is constant between 13 and 14 volts. A manual switch may allow the voltage setting to increase or decrease to change the charge rate. These designs are found in inexpensive chargers, and the technician must use them with care because they can cause overcharging of batteries. **Trickle chargers**, which charge a battery at a low-ampere rate, are made following this design. Slow charging or trickle charging a battery is less stressful on a battery than fast charging because a low-ampere charge does not excessively heat and gas a battery.

- **Constant-current chargers** automatically vary the voltage applied to the battery to maintain a constant amperage flow into the battery. These vary the voltage to maintain the constant current into the battery as its resistance changes. Also called series chargers, several batteries can be connected together in series and charged together. These are premium, high-end chargers not commonly found in service facilities.
- **Taper-current chargers**, like that in **FIGURE 12-44**, are the chargers most commonly found in repair shops. Either constant voltage or constant amperage is applied to the battery through a manually adjusted current selection switch. Charger current only diminishes as the cell voltage increases. These chargers can cause serious damage to batteries through overcharging if the charge current is adjusted too high. Timers can automatically shut off the charger to prevent this condition.
- **Pulse type chargers** are recommended to recover sulfated batteries and send current into the battery in pulses of 1-second cycles. Varying the voltage and length of time a pulse is applied to the battery controls the charging rate. During the charging process, a short rest period of 20 to

FIGURE 12-44 Take care with this type of basic constant-voltage charger to ensure overcharging does not occur.

30 milliseconds between pulses improves the quality of chemical reactions in the battery.

- The output of an **intelligent charger** varies with the sensed condition of a battery. This means the charger, like the one in **FIGURE 12-45**, monitors battery voltage and temperature and varies its output based on these variables. The charger also calculates the optimal charge current and varies it over the charging period, depending on the type of battery connected to it. Charging terminates when the voltage, temperature, or charge time indicates a full charge. VRLA batteries are best suited to these types of chargers. These chargers can be left connected indefinitely without overcharging, as they can maintain a float charge. This means the charging voltage floats at zero or a very minimal charge voltage until it senses that the battery voltage has fallen, and then resumes charging.

FIGURE 12-45 Note the timer on the right-hand side of this taper-current charger; to reduce the risk of overcharging.

Removing the negative battery terminal while charging a battery reduces the risk of burning up any electronic devices on the vehicle if the ignition key is on.

Charging Battery Banks: Series or Parallel

Manufacturers install multiple batteries in most heavy equipment vehicles to provide additional cranking amperage. Knowing how the batteries are connected together will determine how to properly connect a battery charger. Batteries can be connected in series

FIGURE 12-46 This intelligent charger automatically controls the charge going to the battery. You can also select different battery types to ensure you are applying the correct charge rate for the battery you select.

or parallel. Batteries connected in series are connected in line with each other, with the positive of one connected to the negative of the other. Batteries connected in parallel are connected side by side, with positive connected to positive and negative to negative.

To charge a 24-volt set of batteries, you need a 24-volt charger to charge all the batteries at the same time. If you only have a 12-volt charger, you have two options: either charge one battery at a time, or reconnect the batteries so they are connected in parallel. To charge batteries, follow the guidelines in

SKILL DRILL 12-5.

SKILL DRILL 12-5 Charging Heavy Equipment Batteries

1. Determine the voltage of the system that needs charging. If you are charging a 12-volt battery, use the 12-volt setting on the charger. If you are charging a 24-volt battery, or two 12-volt batteries connected in series, use the 24-volt setting on the charger; if it has one.
2. Identify the positive and negative terminals. Never simply use the color of the cables to determine the positive or negative terminals; use the + and -, or the Pos and Neg, marks.

3. Visually inspect the battery to ensure there are no cracks, holes, or damage to the casing.
4. Verify that the charger is unplugged from the wall and turned off. Connect the red lead from the charger to the positive battery terminal. Connect the black lead from the charger to the negative battery terminal.
5. Check the settings on the charger; and verify that they are correct for what you are charging.
6. Turn the charger on, and select the automatic setting, if equipped. Select the rate of charge. A slow charger usually charges at a rate of less than 5 amperes. A fast charger charges at a much higher ampere rate, depending on the original battery state of charge; a fast charge should be carried out only under constant supervision.
7. Verify that the voltage and amperage the charger is putting out is proper.
8. Once the battery is charged, turn the charger off. Disconnect the black lead from the negative battery terminal and then the red lead from the positive battery terminal.
9. Allow the battery to stand for at least 5 minutes before testing the battery. Using a load tester or hydrometer; test the charged state of the battery.

SAFETY TIP

When connecting jumper cables, a spark almost always occurs on the last connection you make. That is why it is critical that you make the last connection on the chassis away from the battery and any other flammables. A spark also occurs when you disconnect the first jumper cable connection, so you also need to make that connection somewhere on the chassis.

- Keep your face and body as far back as you can while connecting jumper leads.
- Do not connect the negative cable to the discharged battery, because the spark may blow up the battery. Use only specially designed heavy-duty jumper cables to start a vehicle with a dead battery. Do not try to connect the batteries with any other type of cable.
- Always make sure you wear the appropriate personal protective equipment (PPE) before starting the job. Remember: batteries contain sulfuric acid, and it is very easy to injure yourself.
- Always follow any manufacturer's personal safety instructions to prevent damage to the vehicle you are servicing, and remember if you smell "rotten eggs" *do not* create any spark or flame, as you risk creating an explosion.
- The best practice to follow when charging a battery is "long and low." This means the longer time you take and the lower the amperage, the easier it is on the battery.

► Jump-Starting Equipment

SI2006

Jump-starting a vehicle is the process of using one vehicle with a charged battery to provide electrical energy to start another vehicle that has a discharged battery. Because starting a vehicle requires a high amount of electrical energy, jump-starting a vehicle can put stresses on both vehicles. Taking your time when doing this not only ensures it is done safely, but it is also easier on both electrical systems. The ideal practice once the boosting cables are hooked up is to give the dead machine's battery plenty of time to be charged instead of just hooking up cables and immediately trying to crank the dead machine.

To jump-start heavy equipment vehicles, follow the guidelines in **SKILL DRILL 12-6**.

► Measuring Parasitic Draw

SI2007

All modern vehicles have a small amount of current draw when the ignition is turned off. This charge runs some of the vehicle systems, such as various modules making up the on-board vehicle network. The vehicle computer systems also require a small amount of power to maintain the computer memory while the vehicle is off. The parasitic current draw should be a

SKILL DRILL 12-6 Jump-Starting Heavy Equipment

1. Position the charged battery close enough to the discharged battery that it is within comfortable range of your jumper cables. If the charged battery is in another vehicle, make sure the two vehicles do not touch.
2. Always connect the leads in this order:
 - First, connect the red jumper lead to the positive terminal of the discharged battery in the vehicle you are trying to start. The positive terminal is the one with the plus sign.
 - Next, connect the other end of this lead to the positive terminal of the charged battery.
3. Try to start the vehicle with the discharged battery. If the booster battery does not have enough charge or the jumper cables are too small in diameter to do this, start the engine in the booster vehicle, and allow it to partially charge the discharged battery for several minutes. Try starting the first vehicle again with the booster vehicle's engine running.
4. Disconnect the leads in the reverse order of connecting them. Remove the negative lead from the chassis ground away from the battery. Then disconnect the negative lead from the booster battery. Next remove the positive lead from the booster battery, and lastly disconnect the other positive end from the battery in the vehicle you have just started. If the charging system is working correctly and the battery is in good condition, the battery will recharge while the engine is running. *Note:* A deeply discharged set of batteries can cause the alternator to charge at an excessively high rate for too long, and damage to the alternator can occur.

- Then connect the black jumper lead to the negative terminal of the charged battery. The negative terminal is the one with the minus sign.
- Connect the other end of the negative lead to a good ground on the chassis of the vehicle with the discharged battery, as far away as possible from the battery.
- *Do not* connect the lead to the negative terminal of the discharged battery itself; doing so may cause a dangerous spark.

relatively small amount of current, as excessive draw discharges the battery over a short amount of time.

Parasitic current draw does not necessarily immediately drop to its lowest level the instant the ignition is turned off. This usually occurs over a period of time as various systems go into hibernation or sleep mode, which can take up to a few hours. Consult the manufacturer's service information to determine the maximum allowable parasitic current draw and the time period, after the ignition is turned off, that it takes the modules to go to sleep.

Technicians can measure parasitic current draw in several ways. The most common is using an ammeter capable of measuring milliamps and inserting it in series between the battery post and the battery terminal. The ammeter is usually put in series with the negative battery lead. If the vehicle is equipped with systems or modules that require electronic memory to be maintained, follow the procedure for identifying modules that lose their initialization during battery removal, and maintain or restore electronic memory functions. Note that the timers may reset during the process of disconnecting the battery terminal and connecting the ammeter in series, so you may have to wait for the timers to go back to sleep. If you find excessive parasitic draw, disconnect fuses or systems one at a time while monitoring parasitic current draw to determine the systems causing excessive draw.

Disconnecting the battery can be avoided if a sensitive low-current (that is, milliamps) clamp is available. The low-amp current clamp measures the magnetic field generated by a very small current flow through a wire or cable. Placing the low-amp **current clamp** around the negative battery cable allows you to measure the parasitic draw. If you find excessive parasitic draw, disconnect fuses or systems one at a time while monitoring parasitic current draw to determine the systems causing the excessive draw. To measure parasitic draw with a parasitic load test, follow the guidelines in **SKILL DRILL 12-7**.

► Identify and Test Low-Voltage Disconnect (LVD) Systems

SI2008

Low-voltage disconnect (LVD) systems disconnect a battery load when the voltage of the battery falls below a preset threshold. By doing this, they protect the battery from being excessively discharged and the vehicle from starting. The voltage threshold is normally set between 12.2 and 12.4 volts. Once the battery voltage rises above the set threshold, as it does when the vehicle starts and the alternator commences charging, the load

reconnects automatically. In many cases, LVDs also incorporate an audible alarm and visual warning light to alert the operator before disconnection occurs.

LVDs are connected in series with the load. You test by varying the amount of input voltage around the threshold settings and checking the switching of the output or load to determine if the device switches on and off at the correct voltages. You can conduct testing on the vehicle or off the vehicle on a test bench. Test the LVD on the vehicle by monitoring the input and output, or load voltage, with a DVOM while placing a load across the battery to reduce battery voltage. At the threshold point, the device should turn the power off to the output or load. If two DVOMs are not available, you can use a test lamp to indicate when the output or load voltage drops away as the device switches off, although you should also check the output voltage at some point to ensure the load is receiving full battery voltage when the LVD has the load turned on. Compare the threshold voltages for turn on and off with the manufacturer's specifications. The units are usually sealed and are not serviceable, although some units may provide a means for adjusting threshold voltages.

You can also test the LVD off vehicle using a variable voltage power supply. When using a variable voltage power supply to test an LVD, you duplicate the connections made on the vehicle with the power supply taking the place of the battery. You must ensure that the power supply is capable of supplying enough current to operate the LVD and any load you connect to it on the bench. Once the unit is connected to the power supply and load, as per manufacturer requirements, you can slowly increase and decrease the power supply voltage to test the threshold voltages at which the LVD switches on and off the output or load. To identify and test a low-voltage disconnect system, follow the guidelines in **SKILL DRILL 12-8**.

► Recycling

KI2012

Disposal is a critical issue at the end of every battery's service life. Batteries contain many environmentally damaging chemicals and neurotoxic lead. If they find their way into a landfill, the lead can contaminate the soil and groundwater. For this reason, recycling batteries is mandatory. Many municipalities require battery recycling and levy a "core charge" on every new lead-acid battery sold. The core charge is refunded if an old battery is brought in and exchanged for the new one. This process helps prevent people from discarding batteries in landfills. Check local laws and regulations to ensure that batteries are disposed of correctly.

SKILL DRILL 12-7 Measuring Parasitic Draw on a Battery

1. Research the parasitic draw specifications in the appropriate service information for the vehicle you are diagnosing. Typically this is between 0.035 and 0.050 amp (35–50 milliamps).
2. Connect the low-current clamp around (or insert the ammeter in series with) the negative battery cable, and measure the parasitic draw. Compare the parasitic draw with specifications.
3. Disconnect the circuit fuses one at a time to determine the cause of excessive parasitic current draw. Determine any necessary actions.

SKILL DRILL 12-8 Identifying and Testing a Low-Voltage Disconnect (LVD)

1. Research the LVD specifications such as the wiring schematic, device operation, and threshold voltages in the appropriate manufacturer's information.
2. Check the unit on the vehicle for appropriate power and grounds as per the manufacturer's specifications. If no battery voltage is present on the input side of the LVD, check fuses or circuit breakers for correct operation. Rectify any power or ground issues before proceeding to check LVD threshold voltages.
3. If you are testing the unit on a test bench, remove the unit from the vehicle, and connect both power and grounds to the unit as per manufacturer's specifications.
4. Connect a DVOM to the input or battery side connection of the LVD and a second DVOM or test lamp to the output or load-side connection. Note the voltage readings on both the input and output of the LVD.
5. Vary the battery voltage by connecting a variable load to the vehicle battery if testing in the vehicle, or adjust the voltage if using a variable voltage power supply for bench testing.
6. Note the DVOM readings of the threshold voltages from the input of the LVD as the unit turns the load, or output, on and off. Compare the voltage readings with manufacturer's specifications. If the unit does not meet specifications, adjust the threshold voltage if adjustment is possible. If the unit is not adjustable or cannot be adjusted to manufacturer's specifications, then you need to replace the unit.
7. Connect an appropriate load to the output, or load side, of the LVD, and recheck the threshold voltages to ensure the unit is capable of supplying the current with minimal voltage drop between the input and output, or load.
8. Check the operation of any warning lights or bulbs fitted to the unit, ensuring they turn and off as the output, or load, of the LVD is turned on and off. Report any recommendations, and return the unit to normal operation.

► Wrap-Up

Ready for Review

- ▶ There are two types of batteries. Primary batteries cannot be recharged; secondary batteries are rechargeable.
- ▶ Secondary batteries operate using the principles of galvanic reaction and are the most practical for use in heavy equipment vehicle applications.
- ▶ Through a galvanic reaction, electricity is produced when two dissimilar metals are placed in an electrolyte.
- ▶ Batteries have traditionally been used in heavy vehicles to provide starting current and operate electrical accessories if the engine is not running.
- ▶ Batteries are classified by use, application, and chemistry used within the battery. Although lead-acid batteries are most prevalent, hybrid-drive vehicles also make use of nickel-metal hydride and lithium batteries.
- ▶ Lead-acid batteries deliver high rates of current with a higher tolerance for physical and electrical abuse compared to other battery technology. These batteries hold a charge well and when stored dry—without electrolyte—the shelf life is indefinite.
- ▶ Regardless of battery construction, all batteries have the same basic components: case, terminals, plates, cell straps, and electrolyte.
- ▶ A starting, lighting, and ignition (SLI) battery can supply very high discharge currents while maintaining a high voltage, which is useful when cold starting. A lead-acid battery gives high power output for its compact size, and it is rechargeable.
- ▶ Starting, lighting, and ignition (SLI) batteries are designed for a single, short-duration, deep discharge during engine cranking. Deep cycle batteries provide lower amperage current continually for electrical devices and accessories.
- ▶ Lead-acid batteries can be manufactured with electrolyte or dry. Dry batteries can be stored on the shelf for extended periods without the fear of sulfation and are lighter to transport.
- ▶ During charging and discharging, batteries produce hydrogen and oxygen gas caused by the breakdown of water through a process called hydrolysis. These gases require venting and are an explosion hazard.
- ▶ Batteries can be configured into battery banks in cases where larger current or higher-voltage batteries are required.
- ▶ Battery temperature plays an important role in the performance of a battery, and lead-acid batteries have an

ideal operating temperature range. A battery's internal resistance depends on the types of materials used to make the plates and the chemical composition of the electrolyte. A battery's internal resistance determines how quickly a battery can be charged or discharged.

- ▶ Energy density, energy efficiency, life span, SOC window, and the cost in dollars per kWh are all factors in determining the battery technology to use on heavy equipment vehicles.
- ▶ The major battery technologies used in heavy equipment vehicles are nickel-metal hydride (NiMH), lithium, and lead-acid. Each technology has distinct capabilities.
- ▶ NiMH batteries are relatively lightweight and have high power output and long life expectancy, making them a preferred technology for hybrid-drive vehicles.
- ▶ Lithium-ion (Li-ion) batteries are secondary batteries. They are not galvanic, nor do they use an electrolyte solution. Rather, they use a gel, salt, or solid material that replaces electrolyte, so they are immune to leaking.
- ▶ Valve-regulated lead-acid (VRLA) batteries do not use a liquid electrolyte and are completely sealed. As such, they can be installed in any position without leaking.
- ▶ Absorbed glass mat (AGM) batteries use a pressurized battery case that helps recombine oxygen and hydrogen when the battery is recharged. These batteries have a lower internal resistance and a more efficient and faster chemical reaction.
- ▶ A spiral-wound cell battery is a special type of AGM battery that reduces internal resistance even further. Ultracapacitors can supply large bursts of energy and quickly recharge themselves—which make them ideal for use in modern vehicles. As such, they are particularly advantageous in situations requiring regenerative braking and frequent stop-start systems, such as in electric and hybrid vehicles.
- ▶ Compared to lead-acid batteries, ultracapacitors have very low internal resistance and are very quick to absorb a charge.
- ▶ To minimize and prevent battery failure, many vehicles incorporate a battery management system to protect the cells, prolong battery life, and maintain the battery in a state of charge.
- ▶ Battery isolation systems allow the multiple batteries in a battery bank to be separated according to function.
- ▶ When multiple batteries are connected in parallel, batteries eventually charge and discharge unevenly, shortening battery life. Batteries should therefore be rotated through the different positions in the battery compartment, or a balancer (equalizer) should be used to compensate for unequal charges in multiple batteries.
- ▶ Hybrid-drive battery management is much more demanding than the conventional battery management devices due to the harsher environment in which hybrid-drive batteries operate (e.g., rapidly changing charging and discharging conditions).
- ▶ Testing the batteries should be the starting point when diagnosing complaints such as hard starting, slow cranking, or no start; when lights dim when an engine idles or other electrical problems occur; and whenever an alternator is replaced.
- ▶ Keeping the battery and terminals clean is one of the best maintenance practices for batteries.
- ▶ Safety should be the first priority when working around and servicing batteries. The electrolyte inside lead-acid batteries is corrosive and can cause injury to skin and eyes, as well as damage to clothing and the vehicle's parts.
- ▶ Batteries also produce an explosive gas mixture of hydrogen and oxygen during charging and discharging.
- ▶ Batteries fail suddenly due to the loss of a cell or open circuits within the internal connections. Batteries also fail gradually through loss of capacity caused by age, sulfation, extremes in operating temperature, vibration, low electrolyte levels, and grid corrosion.
- ▶ Inspecting, cleaning, and filling (if not maintenance free) are common tasks that should be performed every 6 months to 1 year on top-post batteries and 1–2 years on side-post batteries.
- ▶ The reverse current flow can damage some or all of the electronic control units (ECUs) throughout the vehicle, so it is critical to connect the battery correctly to prevent sending the current in the reverse direction through the electrical system.
- ▶ The capacitance test is the preferred test of battery condition.
- ▶ State of charge testing indicates how charged or discharged a battery is. Low-maintenance or no-maintenance batteries may not provide access to the electrolyte in the cells for state of charge testing.
- ▶ Technicians use hydrometers and refractometers to measure the specific gravity of the electrolyte in the battery during an SOC test.
- ▶ Load testing has long been used to test a battery's capacity and internal condition, but is no longer used. Manufacturers now insist on conductance testing for batteries, particularly any battery returned under warranty.
- ▶ The types of battery chargers include constant-voltage, constant-current, taper-current, pulsed charger, and intelligent chargers.
- ▶ Even with the ignition turned off, all modern vehicles have a small amount of current draw used to run some of the vehicle systems, such as the on-board network modules.
- ▶ The parasitic current draw should be a relatively small amount of current, as excessive draw will discharge the battery over a short amount of time.
- ▶ Correct disposal of batteries by recycling them is good for the environment, and the precious metals can be reclaimed for reuse.

Key Terms

absorbed glass mat (AGM) battery A type of lead-acid battery that uses a thin fiberglass plate to absorb the electrolyte; this prevents the solution from sloshing or separating into layers of heavier acid and water.

amp-hour A measure of how much amperage a battery can continually supply over a 20-hour period without the battery voltage falling below 10.5 volts.

balancers A device designed to adjust battery voltage to compensate for unequal charges in multiple batteries; also called battery equalizers.

battery equalizers A device designed to adjust battery voltage to compensate for unequal charges in multiple batteries; also called balancers.

battery isolator systems A system designed to separate the main starting battery and the auxiliary battery; also called a split charge relay.

battery management system (BMS) A system of electrical devices used to manage battery performance.

cold cranking amps (CCAs) A measurement of the load, in amps, that a battery can deliver for 30 seconds while maintaining a voltage of 1.2 volts per cell (7.2 volts for a 12-volt battery) or higher at 0°F (−18°C).

conductance test A type of battery test that determines the battery's ability to conduct current.

constant-current charger A battery charger that automatically varies the voltage applied to the battery to maintain a constant amperage flow into the battery.

constant-voltage charger A direct current (DC) power that is a step-down transformer with a rectifier to provide the DC voltage to charge.

cranking amps (CAs) A measurement of the load, in amps, that a battery can deliver for 30 seconds while maintaining a voltage of 1.2 volts per cell (7.2 volts for a 12-volt battery) or higher at 32°F (−0°C).

current clamp A device that claps around a conductor to measure current flow. It is often used in conjunction with a digital volt-ohmmeter (DVOM).

deep cycle battery A battery used to deliver a lower, steady level of power for a much longer time.

electrolysis The use of electricity to break down water into hydrogen and oxygen gases.

electrolyte An electrically conductive solution.

flooded lead-acid battery A lead-acid battery in which the plates are immersed in a water-acid electrolyte solution.

galvanic reaction A chemical reaction that produces electricity when two dissimilar metals are placed in an electrolyte.

gassing A situation that occurs when overcharging or rapid charging causes some gas to escape from the battery.

gel cell battery A type of battery to which silica has been added to the electrolyte solution to turn the solution to a gel-like consistency.

hydrolysis The use of electricity to break down water into its oxygen and hydrogen gas components.

intelligent charger A battery charger that varies its output according to the sensed condition of the battery it is charging.

key-off electrical loads Machine electrical loads drawing battery current when the ignition is off.

load test A battery test that subjects the battery to a high rate of discharge; the voltage is then measured after a set time to see how well the battery creates current flow.

low-voltage disconnect (LVD) A device that monitors battery voltage and disconnects noncritical electrical loads when battery voltage level falls below a preset threshold value.

nickel-metal hydride (NiMH) battery A battery in which metal hydroxide forms the negative electrode and nickel oxide forms the positive electrode.

open-circuit voltage (OCV) The difference of the electrical potential between the two terminals of a battery when the battery is disconnected from any circuit.

parasitic draw An electrical load similar to a key-off electrical load except that the current draw is usually unintended or unwanted.

primary battery A battery using chemical reactions that are not reversible, and the battery cannot be recharged.

pulse-type charger A battery charger that sends current into the battery in pulses of 1-second cycles; used to recover sulfated batteries.

reserve capacity Refers to the length of time, measured in minutes, that a battery discharges under a specified load of 25 amps at 26.6°C (80°F) before battery cell voltage drops below 1.75 volts per cell (10.5 volts for a 12-volt battery).

secondary batteries A battery that produces electricity using reversible chemical reactions, allowing the battery to be recharged.

shedding A process that reduces the plate surface area and therefore reduces capacity. Shedding may also produce short circuits between the bottom of positive and negative plates.

smart charger A battery charger with microprocessor-controlled charging rates and times.

spiral-wound cell battery A type of AGM battery in which the positive and negative electrodes are coiled into a tight spiral cell with an absorbent microglass mat placed between the plates.

split charge relay A system designed to separate the main starting battery and the auxiliary battery; also called a battery isolator system.

state of charge test A test that indicates how complete the battery state of charge is, expressed as a percentage of a full charge.

sulfation Refers to a process where sulfate, originally contained in the electrolyte, becomes chemically bound to both battery plates

taper-current charger A battery charger that applies either constant voltage or constant amperage to the battery through a manually adjusted current selection switch.

traction batteries A type of battery construction, commonly used in hybrid electric vehicles, designed to deliver high-amperage loads to electric traction motors.

trickle charger A battery charger that charges at a low-amperage rate.

ultracapacitor A new generation of high-capacity, high-energy density capacitors.

valve-regulated lead-acid (VRLA) batteries A battery design using a gas-tight case that does not permit battery gases or electrolyte to leak from the battery except through a pressure-sensitive safety valve.

Review Questions

- Which of the following is correct concerning battery classifications?
 - Primary battery: chemical reactions are not reversible, and the battery cannot be recharged.
 - Secondary battery: the battery is rechargeable.
 - Both A and B
 - Neither A nor B
- Which of the following is correct concerning types and classification of batteries?
 - Batteries are classified according to what they are used for and how they are made.
 - Batteries are classified by the type of plate material and chemistry used to produce current.
 - Both A and B
 - Neither A nor B
- Which of the following statements is correct concerning deep cycle–deep discharge batteries?
 - Deep cycle batteries are used to deliver a lower, steady level of power for a much longer period of time than an SLI-type battery.
 - Battery plate construction and charging and discharging characteristics of deep cycle batteries are different from those of SLI-type batteries.
 - In heavy vehicles, deep cycle batteries are used to supply current to constantly powered accessories, such as driver- and vehicle-communication devices.
 - All of the choices are correct.
- Which of the following statements is correct concerning separator plates?
 - To prevent the battery positive and negative plate from touching and short circuiting, separator plates are placed between each plate in every cell.
 - Separator plates are very thin, porous, glass fiber plates allowing electrolyte to diffuse freely throughout the cell and at the same time preventing plate contact.
 - Both A and B
 - Neither A nor B
- One of the characteristics of low- or no-maintenance batteries is _____.
 - greater corrosion
 - higher electrical reserve capacity
 - lower water usage
 - slow discharge rate due to parasitic loss
- Which of the following statements is correct concerning battery selection?
 - The CCA rating of the battery is the most important rating considered when selecting batteries.
 - In colder weather, engines are also harder to crank due to increased resistance from oil thickening.
 - BCI estimates diesel engines require 220–300% more battery power than a similar gasoline engine.
 - All of the choices are correct.
- Which of the following is *not* correct concerning lithium-ion batteries?
 - Lithium-ion batteries have liquid electrolyte similar to lead-acid batteries.
 - Currently there are dozens of different cell chemistries used to produce lithium-ion batteries.
 - Regardless of their specific chemistry, lithium batteries have a higher energy density than other battery types, such as lead-acid, nickel-cadmium, and NiMH.
 - Popular Li-ion chemistries incorporate electrodes made from lithium combined with phosphate, cobalt, carbon, nickel, and manganese oxide.
- Which of the following is *not* correct concerning gel cell batteries?
 - Gel cell batteries can be considered spill-proof batteries.
 - A fully charged gel cell battery has an open-circuit voltage of at least 12.55 volts.
 - Gel cell batteries are created by adding silica powder to the electrolyte, which turns the liquid into the consistency of petroleum jelly; hence the name “gel cells.”
 - Gel cell batteries are sensitive to overcharging and can be ruined by overcharging.
- Which of the following is correct concerning valve-regulated lead-acid batteries (VRLA)?
 - With a VRLA battery, there is no need to add distilled water.
 - With a VRLA battery, there is no cable corrosion.
 - With a VRLA battery, there is the longest service life of all battery types.
 - All of the choices are correct.

ASE Technician A/Technician B Style Questions

- Technician A says that hybrid electric vehicles are not commonplace in industrial settings, but are likely to be in the future. Technician B says that heavy equipment, particularly diesel-powered equipment, uses multiple batteries connected in series or parallel to produce adequate starting current. Who is correct?
 - Technician A
 - Technician B
 - Both A and B
 - Neither A nor B
- Technician A says that a fully charged 12-volt battery is 12.00 volts. Technician B says that connecting cells together in series allows batteries to be produced in a variety of output voltage. Who is correct?
 - Technician A
 - Technician B

- c. Both A and B
 - d. Neither A nor B
- 3. Technician A says that the primary difference between deep cycle batteries and SLI is the thickness of the plates. Technician B says that deeply discharging SLI batteries dramatically shortens their service life. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
- 4. Technician A says that during charging and discharging, water in the electrolyte is broken apart into its constituent hydrogen and oxygen in a process called electrolysis. Technician B says if battery electrolyte is too low, the plates dry out, and the increased acid concentration of electrolyte permanently damages the grids. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
- 5. Technician A says that the demand for advanced battery technology in commercial vehicles is growing. Technician B says that not only do the increasingly popular hybrid electric vehicles require advanced batteries, but heavy-duty commercial vehicles also have a greater need for electrical storage capacity to run accessories. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
- 6. Technician A says that a smart charger is a battery charger in which microprocessors control charging rates and times. Technician B says that AGM state of charge can be tested with a battery hydrometer. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
- 7. Technician A says that batteries should be the starting point when diagnosing complaints such as hard starting, slow cranking, or no start. Technician B says that dirt on top of the battery does not cause premature self-discharge of the battery. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
- 8. Technician A says you should never create a low-resistance connection or short across the battery terminals. Technician B says to always wear protective clothing such as rubber gloves and goggles or full-face shields when handling batteries. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
- 9. Technician A says that if electrolyte is lost due to spillage, then the battery should be topped up with electrolyte. Technician B says that if electrolyte level is lost through evaporation, then tap water should be added. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
- 10. Technician A says that a fully charged battery should have an open-circuit voltage of 12.25 volts. Technician B says that if the battery has been recently charged, a light load applied to the battery for a few minutes will remove a surface charge.
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B

CHAPTER 13

Electric Motors

Knowledge Objectives

After reading this chapter, you will be able to:

- **K13001** Identify and describe the applications of AC motors.
- **K13002** Identify and explain the difference between AC induction and synchronous motors.
- **K13003** Identify and describe the difference between single-phase and three-phase induction motors.
- **K13004** Describe and explain the construction, functions, applications, and operating principles of AC motors.

Skills Objectives

There are no Skills Objectives for this chapter.

► Introduction to Electric Motors

Manufacturers producing off-road heavy equipment use electric motors for electric-only propulsion and hybrid-drive systems combined with diesel engine (FIGURE 13-1). Electric-only systems using battery power are frequently used in forklifts and in electric powertrains for mining vehicles, and are moving the industry from reliance on underground diesel engines to zero-emission vehicles. Electric-drive and hybrid technology for the heavy construction market is relatively new, with the first hybrid tractors such as Cat's D7E and Komatsu's HB215LC-1 excavator appearing in 2010. However, diesel electric drives have been around since the 1930s and are the main propulsion configuration for locomotives and mining trucks hauling in high-production mining and heavy-duty construction projects (FIGURE 13-2). These machines haul

anywhere from 40 to 100 tons of material in quarries or road-building work, using electric traction motors (FIGURE 13-3). The ultra-class trucks hauling 300–450 tons exclusively use diesel electric hybrid-drive systems. Technicians will encounter electric motors in other applications powering hydraulic pumps, steering systems, large hydraulic cooling fans, and driving compressors for air conditioning in operator cabs. Understanding electric motor operating principles and troubleshooting techniques is important, then, to a technician wanting a broad range of skills to diagnose and service problems caused by various types of electric motors and propulsion systems. In order to help build technician competencies associated with making repairs and giving service recommendations, this chapter examines the various applications of electric motors, their types, and the architecture of

FIGURE 13-1 Many manufacturers are producing hybrid machines that use electric motors for propulsion, this strategy allows the engine to run at a more efficient RPM which saves fuel and therefore reduces emissions.

FIGURE 13-2 Locomotives use diesel electric generators to supply current to electric traction motors located at the wheels.

FIGURE 13-3 Diesel-driven AC generators supply current to electric drive motors of this truck.

electric-drive systems. Principles of operation of DC and AC motors, plus safety and service-related information, are covered to further enhance technical understanding and skills. Note that working with high-voltage electric current is potentially lethal. For this reason, electrical safety codes in most jurisdictions require technicians to have specialized electrician qualifications for working on circuits having more than 50 volts. Information in this chapter is to provide background information for understanding electric motors and servicing them in compliance with legislated safety and labor code standards.

► Advantages of Electric Motors

K13001

By definition, motors are devices that take any form of energy, other than combustion, and convert it into mechanical energy. Air, fluid, and vacuum are just a few of the different types of energy used to supply power to a motor. More specifically, electric motors use electrical energy and convert it into rotating mechanical energy. Because electric motors supply rotational energy like engines, they are used in place of engines and have advantages over engines. A few of these advantages include:

- Lower initial purchase cost and less complex construction
- More energy efficient than engines
- Fewer maintenance requirements
- Longer service life, as electric motors are designed for as many as 35,000 hours of operation
- Capable of producing maximum torque at low speeds and even stall speeds
- Smoother increase in speed and torque from 0 rpm to maximum
- Capable of providing retarding force to a machine
- Capable of generating electrical energy (when operating either as retarders or in a regenerative mode to charge batteries)
- Relatively inexpensive to operate—electricity is cheaper than liquid fuel such as diesel or gasoline
- Easier to start and simpler to operate—only a switch to turn on and off or an electronic controller is needed to regulate speed
- Capable of starting under a moderate load
- Capable of withstanding temporary overloaded conditions that severely reduce speed and may even stall the motor
- More compact in design, requiring smaller area and no additional support systems such as fuel tanks or radiators
- Low noise level
- No exhaust fumes
- Fewer safety hazards.

Auxiliary motors refer to motor functions driving auxiliary devices directly coupled, or driven by motors from a belt or gear drive. Examples of auxiliary motors include those driving air-conditioning compressors; cooling fans; and pumps for water, oil, or operating equipment such as hoisting devices. The use of auxiliary motors can promote more efficient engine operation. For example, when the AC compressor is driven electrically, it provides an acceptable reason for operators to shut off an engine during idling.

When used in a propulsion drive system, electric motors are referred to as **traction motors**. Combined with diesel electric-drive systems or hybrid-drive systems, motors are used to lower operating costs of traditional diesel equipment and reduce carbon emissions. In **series-type hybrid electric drive** systems where an engine drives a generator, which in turns supplies power to an electric motor, the bulk of efficiency gains is achieved by enabling the engine to work constantly within a narrow speed range.

Electric traction motors vary drive torque and speed to final drives with minimal change to the engine speed (**FIGURE 13-4**). Operating the engine inside a narrow speed range reduces fuel consumption because the speed range chosen is an optimal point of efficiency for an engine. In a series-parallel hybrid

FIGURE 13-4 Two electric motors and a smaller auxiliary motor located on top of this final drive supply propulsion force to an off-road machine.

configuration, where the engine and motor combine to supply drive torque to supplement engine power output, electric motors can boost the drive torque from stand-still or add drive torque above an engine’s base operating capabilities (**FIGURE 13-5**). Drive torque supplemented from an electric motor allows operators to obtain better engine response and encourages operation in a lower speed range. This in turn lowers power transmitted through the driveline and reduces fuel consumption.

Electric motors for battery electric machines such as forklifts or mine scooptrams for loading and hauling material are very power dense with high torque from a compact design. In the latest models, electric motors can produce three times the power of a comparable diesel 1.5-yard equivalent (**TABLE 13-1**). But the biggest benefit is that battery-powered equipment like this is the consequence of eliminating engine emissions. Diesel emissions are the major health hazard, and some mines have as many as 150 diesel machines working underground. According to one equipment manufacturer, several ventilation shafts, costing \$50–100 million dollars each and needed to clear emissions, can be eliminated for underground mines. Additionally, 40–90% of total energy costs that are expended ventilating mines are substantially reduced when battery-powered electric-drive machines are used.

Diesel electric locomotives and heavy haul trucks popularized the use of electric-drive systems. Electric-drive motors simplified the way power is transmitted more efficiently to the wheels while greatly reducing maintenance requirements. Transmitting power through a transmission requiring an enormous number of gears and elaborate shifting mechanisms would be impractical (**FIGURE 13-6**). Braking and tire wear can be further reduced with electric drive motors. Braking and tire wear are reduced because the electric motor, when operated like a generator, can absorb energy and replace foundation brakes. Any electric motor, whether it is operated using AC or DC current, can also be used to generate current. A small amount

TABLE 13-1 Comparing Efficiency of Motors with Engines

FIGURE 13-5 Configuration of a series-type hybrid powertrain and hydraulic system.

FIGURE 13-6 Locomotives and other diesel electric machines drive AC generators. AC current is converted to DC and then inverted again to AC to change voltage and frequency to better regulate propulsion motor operation.

FIGURE 13-7 Any AC motor can be instantly converted to a generator and used as an auxiliary braking system. The retarder will often convert electrical energy to heat, using a resistor bank.

of current supplied to the motor when it is being driven by a mechanical input will change it from motoring to electric power generation. When operated as a generator, the motor effectively turns into an energy absorbing brake, which in turn reduces foundation brake wear. When two drive motors are used to steer a machine, the differential torque control enhances turning capabilities and reduces tire wear. The generator function, which operates as an automatic retarder, can keep the machine within speed limits at all times. Anti-rollback supplied by the same retarder-generator function provides one-pedal control on hills and cruise control functions in both propel and retard operating modes (FIGURE 13-7).

When large lead-acid batteries are used on a machine such as an electric forklift, the batteries indirectly provide the benefit of providing more traction force to tires. Heavy batteries function as a counterweight to provide a stable counterbalancing force to oppose the lifted load.

► Classification of Electric Motors

K13002

The widest classification of electric motors is according to the type of electrical current used:

- Alternating current (AC) motors
- Direct current (DC) motors

Both types of motors are used in off-road machines. DC current motors are especially useful because they directly power through batteries. DC motor control is also simplified because speed and torque are controlled by varying current flow through motor windings, using a simple rheostat. A large variety of DC motor designs are used everywhere, from starting motors to blower motor fans, to powering pumps for fuel

FIGURE 13-8 A cross-sectional view of a DC electric motor. Note the commutator and brushes.

or coolant (**FIGURE 13-8**). The arrangement of windings and whether they use permanent magnets generally classifies DC motors. The construction and operation of these motors is more extensively covered in Chapter 11. Although they have many applications, DC motors are generally not often used for propulsion systems, as they use a commutator and brushes to conduct current through the armature, the rotating part of the motor. Brushes eventually wear out, and the increased complexity of the motors makes them more expensive. Torque output compared to motor weight is less for DC motors (**FIGURE 13-9**).

AC Motors

AC motors are the most common type used for traction motors. One reason for the popularity is the AC motor has a simpler design with no moving parts to wear out except bearings supporting the motor shaft (**FIGURE 13-10**). Unlike DC motors, AC motors do not use commutators or brushes to switch the direction of current flow through an armature. Instead, the continuously changing polarity of AC current creates a rotating magnetic field movement inside an AC motor.

FIGURE 13-9 Classifications of electric motors.

FIGURE 13-10 Major components of an AC induction motor.

A second major reason for using AC motors is the efficiency of AC current transmission. AC current is transmitted much farther than DC current, with little resistance. This property explains why municipalities use AC current to transmit electricity to homes and industry over long distances with comparably little power loss. To understand this, recall that electrons in AC current constantly moves back and forth in a circuit. There is no incremental forward movement of electrons in an AC conductor; unlike a DC conductor where electrons move continuously in only one direction—from negative to positive. In AC conductors, the movement of electrons cycle or pulses back and forth, causing the polarity of the conductor to continuously change (**FIGURE 13-11**). In one moment of time, electrons in an AC circuit are pulled and subsequently pushed, then pulled and pushed all over again. Power transmission of AC current in North America specifies a cycle switching time of 60 times per second for the push-pull polarity change of AC current. An electrical force exerting one push-and-pull cycle on the electrons produces a familiar sine wave if the circuit polarity is graphed over time. This continuously changing polarity of AC current, which can be 60 cycles per second, or 60 hertz (Hz), accounts for the efficiency of AC circuits. In AC circuits, electron energy isn't used up migrating electrons from one atom to the next along the length of the circuit to its end. Electrons in AC conductors stay in the same area. Resistance in an AC circuit, called **impedance**, is proportional to the frequency of polarity change. In fact, using higher frequency of polarity change or Hz reduces impedance or resistance in an AC circuit. In other words, the higher the AC current's frequency, the less resistance AC current has in a circuit.

Reduced circuit impedance and more efficient transmission isn't the only reason for using AC motors. The biggest advantage of AC motors is their simplicity. Because they have only one moving part, the rotor, they are more economical to build, operate more quietly with greater reliability. AC current simplifies motor construction by providing a constantly changing polarity. This eliminates the need for a commutator used in DC motors. In the most common AC motor designs, the AC current produces a continuously changing polarity of the magnetic fields inside the motor. AC current frequency regulates the speed of AC electric motors, with higher frequency corresponding to faster motor speed. This means AC motor speed control requires frequency regulation.

FIGURE 13-11 Comparing AC and DC electric current waveforms.

► AC Current Types

KI3003

AC current has been used to power homes and industry since the 1890s, when industrialist George Westinghouse popularized the AC electric current type, invented by Nickolas Tesla. A major competitor using DC current also supplied electricity. Thomas Edison's, Edison electric company, later merged with another electric company to become General Electric, which competed with Westinghouse for domination of the power generation and supply. The current war fought between the two companies determined whether AC or DC current would ultimately be the electric current of choice for consumers and industry. The efficiency of AC current transmission won out, and AC current is delivered as two subtypes: single and three-phase current (**FIGURE 13-12**).

To diagnose the cause of a motor not starting, follow the steps in **SKILL DRILL 13-1**.

Single-Phase AC Current

Single-phase current, also known as house current, is used to power lights and small appliances. It's called single phase because of the use of two wires, one neutral and one power, which provide a pathway for electricity flow between them. The description of single phase is also derived from the appearance of the sine wave-shaped waveform of alternating current. Single-phase AC power voltage peaks at 90 degrees and 270 degrees when it completes a cycle time, measured in 360 degrees. This means at a starting point of 0 degrees, the voltage between the two wires is 0 volts and rises to +120 volts peak after 90 degrees. Voltage between the two wires falls to 0 volts after 120 degrees of cycle time and then peaks again to -120 volts after its polarity switches negative at 270 degrees of cycle time. Ninety degrees later, the current has a voltage of 0 volts before another cycle begins. Note that the peak voltage is briefly +120 volts during one cycle (**FIGURE 13-13**).

FIGURE 13-12 Single-phase versus three-phase current.

SKILL DRILL 13-1 Diagnosing a No-Start Split-Phase Motor

To troubleshoot a no-start condition of split-phase motor, use the following procedure as a general guideline:

1. Switch off the power to the motor, and lock out any electrical switch while working on the motor.
2. Visually inspect the motor for seizure, burned wiring, damage, or evidence the motor stator is burned out. Replace the motor if it is damaged.
3. Locate and inspect the motor thermal switch. Reset a manual thermal switch if it is tripped, and switch the motor on to recheck motor operation.
4. If the motor remains inoperative, carefully check for line voltage at the motor's power terminals. Use a multimeter and set for AC voltage RMS. Alternatively, use an AC test light suited for the line voltage. If the voltage is not within 10% of the voltage listed on the motor's data plate, inspect the current supply line to the motor. If the voltage is adequate, switch off the power to the motor and lock out the switch.
5. With power switched off, use an ohmmeter to measure the resistance of the main and auxiliary windings by placing the meter leads across the power terminals of the motor.

A minimum amount of resistance must be present. An ohmmeter measurement of 0 ohms resistance indicates an internal short circuit. A measurement of infinite resistance indicates a defective centrifugal switch, or open starting and main winding. The highest resistance reading is measured between the start and run terminals. A middle resistance reading is between the start and neutral terminals. The lowest resistance reading is between the run and neutral terminals.

6. If the motor leads have infinite resistance, remove the motor end cap or end bell. Visually inspect the centrifugal switch operation and for signs of burning or broken springs. Replace the switch if it is damaged. Check the switch operation by manually operating the switch while using a multimeter to determine whether it is opening and closing correctly.
7. Probe the motor leads at the centrifugal switch while checking to determine whether the resistance of the leads changes when operating the switch. If the resistance of the leads does not change when manually operating the switch, the motor is likely defective and should be replaced.

FIGURE 13-13 An AC sine wave shows the polarity peaks at 120 volts positive, falls to zero, then moves to -120 volts before returning to 0 volts at the end of the cycle.

Any other time, it is less than 120 volts, rising and falling as it approaches a polarity change. Voltage peaks and dips mean electric power is not supplied at a constant rate like DC current. The cyclical change in voltage and polarity of the power conductor takes place 60 times per second in North American power systems—50 times or hertz (Hz) in Europe. Single-phase conductors are color-coded according to electrical code for each country where the wiring is used. Generally, in North America, black is designated for power and white for the neutral conductor. In Europe, blue is neutral, with black or brown designated the power wire.

Single-phase current is adequate for operating electric motors up to about 5 horsepower. But the lower average voltage during a cycle means motors and other devices using single phase require more amperage to compensate for the lower peak average voltage compared to three-phase current described in the next section (**FIGURE 13-14**). Single-phase current is supplied at 120 or 240 volts, always using 0 volts as a reference. With 120 volts, the peak voltage is 120 volts measured from 0 volts to +120 volts, or 0 volts to -120-volt peaks. Similarly, 240 volts is measured from 0-volts to either positive or negative volt peak.

FIGURE 13-14 A single AC waveform only peaks two times during a cycle, and average voltage is less than its peaks.

► TECHNICIAN TIP

Measuring AC Voltage

It is not of everyday practical application, but AC voltmeters measure AC voltage using the **root mean square (RMS)** calculation. Stated mathematically: $V_{AC} = V_{RMS} \times \sqrt{2}$. Because AC voltage peaks are not constant or continuous like DC current, the RMS measurement method provides a comparable measurement of AC current to DC current. The RMS value of AC voltage refers to the effective value of AC voltage or current and not the wave peak positive-to-wave peak negative difference in voltage. AC voltage calculated using RMS provides the equivalent AC voltage measurement to DC voltage that should have the same power or effect (**FIGURE 13-15**). For example, AC voltage measured using RMS method produces the same heating effect as DC current. This means a bulb connected to a 10 V RMS AC supply will shine with the same brightness when connected to a steady 10 V DC supply. This assumes the power source is a pure sine wave. Stated another way, the peak value of household voltage in North America is about $120 \times \sqrt{2}$, or about 170 volts measured from positive to negative voltage peak.

Three-Phase AC Current

Because AC current waveform has peaks and valleys, it contains less energy than DC current that remains constant. To improve the efficiency of devices using AC current, three-phase AC current can be used. Three-phase current provides more uniform delivery of current than single phase (**FIGURE 13-16**). Unlike single-phase current supplying AC using two wires, a neutral

RMS Voltage Equivalent

FIGURE 13-15 AC voltage is measured using an RMS calculation that gives it the same energy value as DC voltage.

FIGURE 13-16 Three-phase current peaks more often per cycle than single phase.

and power wire and perhaps a third ground wire for safety, three-phase current uses five wires; three wires supply power, and the other two are a neutral and often a ground wire. When graphed over a 360-degree cycle time, three power wires, each 120 degrees out of phase with one another have entered the cycle. When a whole cycle of 360 degrees has completed, three phases of power have each peaked in voltage twice. That means there are six power peaks in three-phase current compared to just two in single-phase current. With a three-phase current supply, a steadier flow of power is delivered at a more regular rate, which contains more energy. Practically this means three-phase current can supply more power or energy per unit of time than single-phase current. When comparing motors, a single-phase 5 hp motor draws significantly more amperage than an equivalent 5 hp motor operating using three-phase motor, making three-phase power a more efficient choice for industrial applications.

To measure three-phase current draw, follow the steps in

SKILL DRILL 13-2.

SKILL DRILL 13-2 Diagnosing Split-Phase Motor Capacitors

Starting capacitors are used by split-phase motors to initiate rotor rotation. A defective capacitor will prevent the motor from turning to start. However, manually turning the motor and causing it to rotate enables the motor to spin up to speed.

To troubleshoot a capacitor motor, use the following procedure as a general guideline:

1. Switch off the power to the motor and lock out any electrical switch while working on the motor.
2. Remove the cover of the starting capacitor that is usually located on the outside of the motor frame.

3. Visually inspect the capacitor for leaking oil, cracks, dents, or bulges. Replace the capacitor if any damage is observed.
4. Before a capacitor can be tested, any electrical charge it hold has to be drained by shorting the two terminals of the capacitor, using a resistor and jumper wire. A capacitor in good working will hold a charge for days after the power is removed.
5. Use caution to avoid making contact with the capacitor terminals. A capacitor can be discharged while it is attached to the motor frame or disconnected. Connect a 20K ohm resistor across the capacitor's two terminals, using a jumper wires. A good capacitor will produce

SKILL DRILL 13-2 Diagnosing Split-Phase Motor Capacitors (Continued)

a strong spark when its terminals are shorted together. Allow the charge to dissipate through the resistor for at least 5 seconds before disconnecting and removing the capacitor.

- 6. After a capacitor is discharged, measure the resistance of the capacitor; using an ohmmeter. Connect the ohmmeter leads to the capacitor terminals.

Good Capacitor: A good capacitor initially shows a low resistance reading that gradually climbs until the resistance is

infinite. This happens because the small amount of current from the meter charges the capacitor, which progressively increases its resistance.

Defective Capacitor: A shorted capacitor has low or no resistance and remains like that when the meter is connected. A defective open capacitor shows infinite resistance even after it is discharged.

Three-Phase Conductor Color Codes

Conductors of a three-phase system are usually identified by a color code to allow technicians to calculate and evenly balance the loading or amperage drawn by each phase of a three-phase circuit (TABLE 13-2). Color-coding is also necessary to ensure the correct direction of rotation for motors. Rotation direction of three-phase motors is obtained by changing the connection of each phase to the motor stator windings. In addition to the superior efficiency, the ability to change direction of three-phase

motors is an advantage and not something single-phase motors can perform. Each country uses its own color code to identify the phase of each conductor, and the neutral and ground circuits. Conductor colors conform to International Standard IEC 60446. However, the large discrepancy between color codes means it's very important to understand how to properly identify current phasing and related conductor color codes to prevent damage to circuits, devices, and anyone using the electrical devices. When the phases are connected correctly, current will never flow through the neutral wire that is also often connected to the ground wire in commercial or residential facility wiring. In the WYE phase distribution configuration most widely used in North America, three-phase current is designated 208Y/120 (FIGURE 13-17). This abbreviation means that the power line-to-line (L-L) voltage is 208 VAC in a WYE configuration and the line to neutral (L-N) voltage is 120 VAC (FIGURE 13-18). It is beyond the scope of this textbook to explain how to differentiate among other power distribution configurations and the techniques used to identify the line voltages.

TABLE 13-2 U.S. AC Power Circuit Wiring Color Codes

Function	Label	Color, Common	Alternative Color
Protective ground	PG	Bare, green, or green-yellow	Green
Neutral	N	White	Gray
Line, single phase	L	Black or red (2nd hot)	
Line, three-phase	L1	Black	Brown
Line, three-phase	L2	Red	Orange
Line, three-phase	L3	Blue	Yellow

NEMA Nomenclature for Electrical Connectors

When machines with electric motors are connected with cords, such as in underground mining, they use U.S. National

FIGURE 13-17 Connection points for a wye-wound three-phase motor.

FIGURE 13-18 This electric motor tag contains information designating the motor as three-phase and listing the voltage at which the motor operates.

Electrical Manufacturers Association, or NEMA, compliant wiring devices. NEMA standard connectors are made in current ratings from 15 to 60 amps, with voltage ratings from 125 to 600 volts, each using various combinations of blade shapes and orientation. The connector configurations use dimensions to design non-interchangeable plugs and receptacles unique for each combination of voltage, amperage, and grounding system. A simple alphanumeric code provides information about the number of current-carrying conductors, the application voltage, and whether it is used for

single- or three-phase power (**FIGURE 13-19**). Letters at the beginning and end of the code are used to indicate whether the connector is a locking type and whether it is a male or female connector.

Twist lock devices all start with the letter “L,” using curved blades and twist-lock connectors (**FIGURE 13-20**). Twist-lock electrical connectors are required for heavy industrial and commercial equipment, to protect against accidental disconnection. After a twist-lock plug inserts into a twist-lock receptacle, the plug is twisted, and the curved blades latch into the receptacle. Unlatching the plug requires twisting the plug in the opposite direction.

Conductors

Orange insulation identifies all high-voltage conductors. This stands out on a machine and should alert technicians to potential danger. High-voltage conductors are also most likely the largest gauge wires on the machine: at least 2/0 gauge or larger. If they need to be larger than 4/0, they are identified by MCM numbers, such as 313 or 777. MCM is an abbreviation for “1000 circular mils.” This equates to the cross-sectional diameter in mils. One mil is the equivalent cross-sectional area of a 0.001 in. diameter circle. If a wire is 313 MCM (KCmil), this equates to 313,000 mils.

These high-voltage conductors are multilayered, starting with the current-carrying copper core; then comes rubber insulation; then Mylar tape; then a braided, stainless steel grounding shield; and finally an outer orange nylon cover (**FIGURE 13-21**).

► **TECHNICIAN TIP**

Servicing High Voltage Conductors

High-voltage conductors should never be modified and, if damaged, they should be replaced and never repaired (FIGURE 13-22). Conductors usually have heavy-duty connectors that must be torqued to specification to ensure they stay tight. If a connector comes loose, it will eventually start arcing, which causes a voltage drop that causes an operational problem and could end up burning off. Any time a high-voltage connector is assembled, it must be clean and dry. After the connection assembly is completed, the manufacturer may require an application of special sealant to minimize the likelihood of corrosion.

FIGURE 13-22 Example of high voltage conductors arranged in an insulated stand-off bracket.

► **AC Motor Construction and Classification**

K13004

All AC motors typically consists of two basic parts. The first is an outside stationary component, called a **stator**, that uses coiled wire supplied with alternating current to produce a magnetic field. The second moving component, called the **rotor**, is attached to the output shaft. Rotors correspond to an armature in a DC motor. Like all other electric motors, all AC motors use principles of magnetic repulsion to produce rotational movement (FIGURE 13-23). Magnetic fields in the rotor and stator oppose one another to produce rotational force (FIGURE 13-24). The rotor's magnetic fields are commonly created by permanent magnets, magnetic induction, or electromagnetic windings. The magnetic field of the stator winding can appear to have movement due to the use of alternating current. Remember that the direction of current flow in a conductor creates a magnetic field with poles, so a winding in the stator may have a north or south orientation depending on the direction of current flow produced by the continuous cycling of AC current. This means that in one moment, moment a single

FIGURE 13-23 Electric motors operate using principles of magnetic repulsion.

FIGURE 13-24 Magnetic poles in the rotor and stator simultaneously pull and push the rotor to produce rotation.

coil of wire may have its north pole oriented closest to the rotor and its south pole oriented towards the outside circumference of the motor (**FIGURE 13-25**). When the direction or polarity of current flow changes 1/120th of a second later, the poles flip. This constant switching back and forth of magnetic poles 120 times a second during a 1-second cycle of a 60-Hz AC current appears as a rotating magnetic field moving around the circumference of the motor as magnetic poles alternate north to south and back again. Observing the apparent movement of magnetic field in relation to AC current polarity in the stator is important, to understand the operation of AC motors.

The two broad categories of AC motors examined in this chapter are classified as either induction or synchronous. Physically, these motors both have a wire-wound stator but are differentiated by the use of a wire-wound rotor used only in the synchronous-type motor. Each of these motors has various subtypes to provide such features as different starting characteristics, rotational speed, torque, and current consumption suitable for unique or specialized applications. The next section examines the construction and operation of these two basic categories of motors.

Induction Motors

Induction motors are the most commonly used type of AC motor. The motor's simple, rugged construction and relatively inexpensive manufacturing costs help popularize this motor used in light, medium, and heavy load applications from ½ hp to 500 hp. Induction motors are most commonly observed driving pumps, machine tools, compressors, conveyers, and large blower motors. Large electric motors driving loads at relatively constant speeds are typically induction-type motors. Both single-phase and three-phase induction motors are built. In addition to the number of power supply conductors, major differences between single-phase and three-phase motors are the use of specialized starting circuits or devices required by single-phase motors only, and the direction of rotation. Single-phase motors only turn in one direction, whereas three-phase motors operate in reverse and forward directions by switching the conductors supplying three phases of stator windings (**FIGURE 13-26**).

Induction motors use electric current in their rotor to produce magnetic fields, but rotors of induction motors are not connected to a supply of electrical current. There are some rare exceptions to this construction detail because unique motors have specialized speed regulation or soft start-up features, but the induction motor derives its name from AC current that is induced in the rotor conductors by the rotating magnetic field of the stator. In other words, induction motors are a broad category of motors having electric current induced in the rotor by magnetic induction (**FIGURE 13-27**).

Again, electric current is induced in the rotor by the changing stator magnetic fields. Magnetic fields in the stator, which continually switch due to the nature of AC current, in turn create magnetic fields in the rotor that automatically arrange themselves to oppose the magnetic fields of the stator. Interaction or

FIGURE 13-25 AC current in the rotor causes the poles to switch magnetic polarity every 1/120th of a second.

FIGURE 13-26 A three-phase stator has three separate circuits forming magnetic fields.

opposition between the magnetic fields in the rotor and stator causes the rotor to turn. To better understand this, remember that magnetic induction produces current flow the same way the secondary circuit of a two-winding transformer or ignition coil receives its power from the primary winding. As current flow in the primary winding builds up and expands its magnetic field, the moving field cuts across the windings of the secondary coil, thereby inducing current flow in the secondary winding (**FIGURE 13-28**). Described another way, the induction motor can be considered a rotating transformer, where the primary winding is the stationary stator, but the secondary winding, the rotor, is free to rotate. Because electric current is only induced in the rotor, the induction motor does not require brushes. If an induction motor is compared to a DC motor, the DC motor can be called a conduction motor. Why? It is because brushes connect DC electric current flow to the armature windings through the commutator bars. Armature current is conducted in a DC motor, not induced as in an AC induction motor.

It's important to remember that the polarity of the magnetic field induced in the rotor will always be opposite the polarity of the stator. **Lenz's law** summarizes this principle, stating that the

FIGURE 13-27 The magnetic field of the stator switches polarity and moves in and out from the motor centerline. The moving magnetic field induces current flow in the rotor bars.

FIGURE 13-28 Current flow is induced in the rotor windings by the stator's moving magnetic field.

FIGURE 13-29 Lenz's law.

current induced in a circuit due to a change or movement of a magnetic field moves in a direction to build up a magnetic field with a polarity opposing the magnetic field of the original inducing current. Both magnetic fields in the rotor and stator exert a mechanical force against each other. (FIGURE 13-29).

Squirrel Cage Rotor

Close to 90% of induction motors use a **squirrel cage rotor**. Having a rotor with the simplest and most rugged type of construction, the squirrel cage rotor resembles an exercise wheel in a rodent cage. It consists of a cylinder with a laminated iron core having parallel slots along its axis for holding the rotor's conductors (FIGURE 13-30). The conductors are not wires, but heavy bars of copper or aluminum or alloys. Bars are placed in the slots and welded or bolted to two thick short-circuiting end rings. The end rings electrically connect the rotor conductors to one another to complete a circuit with other conductor bars in order to establish a magnetic field. No insulation is required between the laminated iron core and the conductor bars. This is because only low voltage current is induced in the rotor bars.

The rotor slots are usually cut at an angle to the shaft axis for two reasons. One is to help the motor run more quietly, because the magnetic fields are slightly skewed to offset alignment with the rotor field coils. This feature tends to reduce a vibration or magnetic hum as the rotor speed changes slightly every time the conductor bars align with the rotor magnetic field. A second

similar reason is the skew of the conductor bars helps to prevent lock-up of the rotor bars with stator coils because of the potential for a synchronization of magnetic attraction forces that can take place when the motor initially starts or is heavily loaded.

Induction Motor Slip

It is impossible for the rotor of an induction motor to turn at the same speed as the apparent rotating magnetic field of the stator. If rotor speed and the apparent movement of the stator's magnetic field were the same, so that the magnetic fields were directly opposite one another, no movement of the rotor could take place since both magnetic fields would lock the motor. A small angle or misalignment must exist between the rotor and the magnetic poles of the stator for two reasons. First, the difference in the angle is necessary to impart a push or repulsion force between the two opposing magnetic fields. The second, more important reason is that an angle must exist between the alignment of the rotor's conductor bars and stator field to induce voltage. If the magnetic field and the conductor bar are on the same plane or exactly parallel to one another, no induction can take place—there must be an angle for induction to take place. (FIGURE 13-31). As the angle between a conductor and magnetic field increase, more current flow is induced in a conductor. The greatest amount of current is induced at an angle of 90 degrees between the conductor and magnet. To maintain an angle, thus enabling the induction motor to run, the rotor must rotate at a speed at least slightly slower than that of the stator's

FIGURE 13-30 Comparing the squirrel cage rotor of an induction-type with a synchronous-type motor.

FIGURE 13-31 When the magnet is in the same plane or parallel to the conductor loop, no current is induced even if the magnet is moved closer and further away.

FIGURE 13-32 An angle between the magnet and conductor is required to induce current flow. The angle is called slip.

rotating magnetic field. This explains why actual induction motor speeds are always listed on a motor tag as 25, 50 or even 75 rpm below maximum no load speed. The difference between the speed of the rotating stator field and the rotor speed is called **slip** (FIGURE 13-32). The smaller the slip, the smaller the angle between the magnetic field and rotor conductor bars. Slip decreases the closer the rotor speed approaches the maximum motor speed. The speed difference, or slip, between actual and synchronized rotor-stator magnetic field speed movement varies from about 0.5% to 5.0%. Even with no load, some slip is present in an induction motor. Because induction motors do not allow the rotor and stator magnetic fields to synchronize speed, induction motors are also called **asynchronous**.

Slip is an important concept in understanding a motor's current consumption and how an induction motor varies its torque

output in response to a load change. Consider first that rotor speed depends on the load applied to the rotor shaft, and the number of poles in a motor. As the load increases, the motor torque must increase to maintain speed. However, slowing the rotor increases the degree of slip. Slowing the rotor also increases the angle or misalignment between the stator magnetic field and magnetic field in the rotor conductors. Increased slip means more current is induced in the rotor because the angle increases between the conductor bars and the stator magnetic field. If more current is induced in the rotor, increased interaction takes place between more powerful rotor magnetic fields and the stator field. Hence, when slip increases, greater magnetic repulsion takes place to instantly increase motor torque. To obtain maximum interaction between the fields, the air gap between the rotor and stator is very small.

Consider too that current flow increases when a load resists rotor shaft rotation. This also is explained by the change in motor slip. As slip approaches near zero, and the rotor catches up to stator field speed, the rotor's magnetic field also induces current flow in the stator winding to oppose current flow through the stator. This takes place because the rotor field is cutting the stator windings faster and at a different angle than when greater slip is present. When the rotor's magnetic fields cut the stators, it produces a **counterelectromotive force (CEMF)** in the stator winding, which opposes current flow through the stator, thus increasing stator resistance to current. CEMF can increase only if the magnetic field cuts through the stator windings more quickly. Therefore, when heavier loads are turned by the induction motor, current flow increases because stator winding resistance caused by CEMF decreases. Only a slight change in speed is necessary to produce the usual current changes required to increase or decrease motor torque. As a result, induction motors are also called constant-speed motors.

Single-Phase Motor Starting Circuits

Single-phase motors will not operate from a stopped position unless they are provided some initial rotating force. When at a stopped position, the stator and rotor magnetic fields would lock together, north to south and south to north. If a single-phase motor described previously were put into operation, it would simply vibrate or hum. You would have to turn it by hand to get it to rotate. Once again, some slip or difference between the angles of magnetic fields is required, or a second magnetic field exerting its force on a portion of the rotor could unbalance the magnetic field. For this reason, single-phase, but not three-phase motors require a starting circuit. The purpose of the circuit or device is to create some unbalanced magnetic field over the rotor to begin to rotate the motor and produce slip. Motors with unique circuits and devices used to unbalance some of the magnetic fields in a **single-phase induction motor** lend the name **split phase** to single-phase motor operation. Split-phase motors are designed to use inductance, capacitance, or resistance to develop starting torque. Two common types of starting devices are examined next.

Capacitor-Start Motors

The most common first type of split-phase induction motor is the **capacitor-start type**. Three components are used: a capacitor; an additional winding, called the starting or auxiliary

FIGURE 13-33 The arrangement of the capacitor, switch main, and starting windings of a capacitor start motor.

winding; and a switch, usually a centrifugal activated switch that closes when the motor stops and opens shortly after it starts. The starting winding is connected in parallel with the main winding but is placed physically at right angles to it. A 90-degree electrical phase difference between the two windings is produced by connecting the auxiliary winding in series with a capacitor and starting switch (**FIGURE 13-33**). When the motor is first energized, the starting switch is closed. This places the capacitor in series with the auxiliary winding. As the capacitor charges and discharges due to the polarity change of AC current cycle, the lead connected to the starting winding has the opposite electrical polarity of the electrical lead into the capacitor. When the proper capacitor is selected, it causes the current in the starting winding to lag the line voltage by about 45 degrees. The effect is that the main and starting windings are each 90 degrees magnetically out of phase with each other. The uneven distribution of magnetic forces exerted by the stator cause the rotor to rotate and speed up. When this happens, the centrifugal switch opens, disconnecting the capacitor. The motor then operates as a single-phase induction motor.

Because the auxiliary winding is only a light winding, the motor does not develop sufficient torque to start heavy loads. As a result, capacitive split-phase start motors are small horsepower motors.

Some heavier motors use a second capacitor, called a run capacitor, to enable two-phase motor operation. After the motor starts, the second capacitor is connected in series to another set of windings connected in parallel to the main windings, but physically offset by 90 degrees (**FIGURE 13-34**). The advantage of a two-phase motor is that single-phase current can be supplied,

FIGURE 13-34 Starting winding and running winding are 90 degrees apart.

FIGURE 13-35 The arrangement of a run and start capacitor to give a motor two-phase operation.

but the motor's direction and speed can be regulated by a motor controller (**FIGURE 13-35**).

To inspect a motor capacitor, follow the steps in **SKILL DRILL 13-3**.

► TECHNICIAN TIP

Defective Capacitors

One of the most common complaints with single-phase motors is a motor that will not start turning or will run only after it's turned by hand. Low starting torque may prevent the motor from rotating and cooling, which opens a thermal protection switch. If the motor will not start, the cause is often a shorted capacitor, an open capacitor, or a capacitor that has a changed value due to deterioration. Capacitors have a limited life and require replacement after they have deteriorated. If a capacitor is short-circuited, constant current flow through the starting winding will cause the winding to overheat or burn out. In two-phase motors, a defective run capacitor will reduce motor torque, decrease maximum motor speed, or cause the motor to only speed up very slowly.

Resistance-Start Motors

Another type of split-phase induction motor is the **resistance-start motor**. Like the capacitor-start motor, the resistive-start motor also has a starting winding at 90 degrees to the main winding. The starting winding is switched in and out of the circuit just as it is in the capacitor-start motor. The difference is that the unbalance condition in the magnetic fields is produced by changing the resistance, or more correctly, the impedance of the windings is unequal. The main winding has a low resistance in contrast to the start winding, which has high resistance. During start-up, the **centrifugal start switch** closes and connects the start winding until the motor speeds up. Once the motor reaches a satisfactory speed, the centrifugal switch disconnects the starting winding from the power line, allowing the motor to continue to run as an induction motor. Resistance-start motors have even less start-up torque than capacitor-start motors.

Three-Phase Motors

Three-phase **squirrel cage induction motors** are widely used as large industrial drive units because they are rugged, reliable,

SKILL DRILL 13-3 Measuring Three-Phase Motor Current

The procedure undertakes measuring the start-up and running current for a three-phase motor while it is connected to a load and comparing the measurements to the motor's data plate or specifications. As motors age, the amperage drawn generally rises because winding insulation resistance drops. Excess current consumption produces extra heat that must be dissipated or motor life is shortened. Uneven amperage drawn between each leg or phase of the motor indicates potential defects or imminent failure.

Note that this exercise is for informational purposes only and should only be done under the proper supervision and

direction of a qualified electrician using prescribed tools and safety practices.

1. Inspect the appearance of the motor. Examine the frame for damage to the cooling fan blade or shaft. Manually rotate the motor shaft to check the bearing condition. Verify that the motor turns freely and smoothly.
2. Collect motor information from the data plate, noting amperage and voltage specification.
3. Measure the resistance between the motor frame and ground. Resistance should be less than 0.5 ohm.
4. Verify supply voltage when the motor is running, measuring the voltage between all legs or phases. The voltage should not vary more than 2% between each phase.
5. If correct voltage is present at the motor, measure the amperage of all three-phases of the motor with an inductive-type current clamp when the motor is under load. Looping the clamp around all three conductors should yield an amperage draw of zero amps because the direction of the magnetic field produced by each phase of current in each leg cancels the current induced by the magnetic fields of the other conductors in each leg cancels the draw of the others.
6. Add the amperage drawn by each phase of the motor, and compare with specifications listed on the motor data plate.

FIGURE 13-36 A three-phase motor stator.

and economical. Three-phase motors are similar in operation and construction to single-phase motors except for the stator. Rather than use a single winding, a three-phase motor uses three separate stator windings arranged 120 degrees offset from one another. Each of the windings is laid over the other and has a main power lead connected to it (FIGURE 13-36). All of the stator windings are connected to one another in one of two methods. The shape the connections form determines whether it is a **wye-wound** or a **delta-wound stator**. As the names suggest, a wye-wound stator has each end of the three windings connected to a

FIGURE 13-37 Comparing wye- and delta-wound stators.

neutral junction point. The other ends are connected to a power leads. A delta-wound stator connects each of the stator ends to form a triangle resembling the Greek letter delta (FIGURE 13-37).

Three of the most commonly used three-phase AC motors are designated as designs B, C, and D by the National Electrical Manufacturers Association (NEMA). They differ primarily in the value of starting torque and in the speed regulation near full load. Each of these designs employs the solid, squirrel cage-type of rotor, and thus there is no electrical connection to the rotor.

Motor Speed and Direction

The four-pole stator design with a synchronous speed of 1,800 rpm is the most common and is available in virtually all power ratings from ¼ hp to 500 hp. Single- and three-phase motor speed is calculated using the formula: rpm = (120 × AC frequency)/Number of poles in the motor:

$$1,800 \text{ rpm} = (120 \times 60)/4$$

Because the number of poles is fixed when the motor is built, the only way to change motor speed, whether it is single or

three phase is to change the frequency of the AC current using a variable-frequency drive (VFD) motor controller. VFDs offer important energy savings when induction motors are used. Induction motors used in variable-torque centrifugal fans and pump and compressor load applications can reduce unnecessary energy consumption when turned slower.

There are, however, some exceptions to the four-pole design: 2-pole (3,600 rpm), 6-pole (1,200 rpm), 8-pole (900 rpm), 10-pole (720 rpm), and 12-pole (600 rpm) designs.

Because this category of induction motor has three phases or windings in the stator, the angles between the magnetic field of the stator and rotor can be electrically altered to reverse the direction of motor rotation. By simply reversing the power connections, the three-phase motor direction of rotation can be either forward or backward. Some motors may use a Hall-effect sensor called the **resolver** that measures the rotor position and speed for a motor controller to properly manage the motor operation. Because overspeed conditions will damage the motor if it is being driven during retarding mode operation, the resolver is a critical sensor for the motor controller to reduce current flow and shut down the system.

Induction Motors as Generators

The two types of motors most readily converted are three-phase squirrel cage induction motors and single-phase capacitor start single-phase induction motors. Turning the motors into generators for braking depends upon the degree of residual magnetism left in the rotor when motoring ends or the supply of current to the motor. By simply driving the motor with some current supplied to the stator, the motor operation will instantly switch to produce electricity. This current supplied to the stator can in turn produce magnetic fields in the rotor, causing the motor to produce alternating current. The frequency of alternating current depends on the speed at which the motor is driving. A three-phase motor will generate three-phase 60-Hz AC current when driven at 1,800 rpm. An AC current of 50 Hz is produced at 1,500 rpm. In generation mode, the maximum amperage is determined by the mass of the stator windings, the electrical load, and the torque driving the rotor at a precise 1,800 or 1,500 rpm. In retarding mode, the motor speed is irregular along with its generator frequency. Current must be rectified to DC current and then back to AC current to drive other electric motors.

Single-phase induction motors are used extensively for smaller loads, such as fans. Although traditionally used in fixed-speed service, induction motors are increasingly being used with variable-frequency drives (VFDs) in variable-speed service.

Synchronous Motor

Synchronous motors are another category of AC motors given the name “synchronous” because unlike asynchronous induction motors, the rotor always attempts to line up its magnetic poles with the rotating magnetic field in the stator. This means the motor does not operate with any slip and feature precise constant speed between no load and full load (**FIGURE 13-38**). The frequency of AC current maintains the motor’s precise speed. For example, clock motors powered by AC current are a type of synchronous motor. Precision speed control allows these

FIGURE 13-38 The specification plate for a synchronous motor for a mine truck. Note that the RPM is a precise 1,800 rpm to produce 60-Hz AC current.

FIGURE 13-39 This synchronous motor for a mine truck can operate as an AC generator.

motors to drive DC generators in welding machines that regulates the welding amperage. Synchronous motors are available in sizes up to 1,000 Hp and are more efficient than induction motors (**FIGURE 13-39**). They may be built as either single-phase or multiphase generator-motor machines. The brief description that follows is based on a three-phase design.

Synchronous motors are constructed with a stator of an induction motor but use a rotor like a DC motor. Unless the motor uses a permanent magnet rotor, DC current is supplied to a wire-wound rotor through slip rings on the rotor shaft. Like the stator of an induction motor, a synchronous motor is constructed from laminated stamped iron plates, which are slotted to receive the windings. The number of poles used in the stator is determined by the requirements of speed. More poles provide more speed, and vice versa. When supplied with three-phase current, the stator forms a magnetic field appearing to revolve at synchronous speed determined by $\text{rpm} = 120 \times \text{Frequency} / \text{Poles}$. Synchronous motors can be electronically controlled to accelerate from zero to synchronous speed by changing the frequency of the stator current.

Energizing the stator with three-phase AC current produces a rotating magnetic field to revolve around the rotor. When the rotor is energized with DC current, the strong rotating magnetic field of the stator attracts the strong rotor field magnetized by DC current. The strong magnetic field on the rotor enables

it to turn a load as it rotates in step, synchronized in speed with the stator's rotating magnetic field.

Unlike a three-phase induction motor, a synchronous motor cannot be started from a standstill by applying AC current alone to the stator. When AC current is supplied, the rotating magnetic field appears instantly and rotates too quickly past the rotor poles to allow it to move. In practice, the rotor is first repelled in one direction and then instantly in another. Torque is only available at synchronous speed, and without assistance, no starting torque is present.

To overcome the problem of no starting torque, large motors operating on commercial power frequency embed a squirrel cage-like induction winding in the rotor. The winding provides adequate torque for starting and acceleration and also operates to dampen motor speed oscillations. Once the rotor nears the synchronous speed, the synchronous rotor field winding is excited, pulling the motor into synchronization. Resistance in the stator circuit can also produce unbalanced magnetic fields needed to move the rotor, just as in single-phase motors. Passing rotor current through a bank of resistors like the resistive-start single-phase motor enables a control circuit to provide starting torque and change rotor speed (FIGURE 13-40). Very large motor systems may include an auxiliary starting motor that accelerates the unloaded synchronous motor before a load is applied.

Common Motor Enclosures

The housings around a motor that support and protect components vary depending on the degree of protection required. Open-type enclosures are made from light-gauge sheet metal surrounding the stator, with end plates to support the shaft bearings. The enclosure allows for excellent ventilation but offers little protection. A variation of the open enclosure protects more of the motor by providing ventilation openings only in the lower part of the housing so that liquids dripping from above cannot enter the motor. A protected enclosure has no provisions for ventilation and is called drip-proof. This type of enclosure may also be considered totally enclosed non-ventilated (TENV). No openings are made in the housing,

with no provisions made for ventilating the motor except for heat-radiating fins cast into the motor frame. Totally enclosed fan-cooled (TEFC) enclosures are like the TENV design, except a cooling fan is mounted at one end of the shaft to move air over the finned housing. TEFC-XP is an explosion proof design similar to the TEFC housing, except special protection prevents sparks from electrical connections or arcing brushes to ignite fires or causing explosions in hazardous environments.

A rough classification of motors by size is used to group motors of similar design:

- Subfractional horsepower: 1–40 millihorsepower (mhp) (0.75 to 30 W)
- Fractional horsepower: 1/20 to 1.0 hp (37 to 746 W)
- Integral horsepower: 1.0 hp (0.75 kW) and larger

Controls for AC Motors

Motor controls must perform several functions depending on the application, size, and the type of the motor involved. Small fractional or subfractional horsepower motors are usually started with a simple switch connecting the motor directly to the line voltage. Larger motors and motors on critical equipment require greater protection and include the following features:

- Ability to start and stop the motor
- Overload protection that would cause the motor to draw dangerously high current levels
- Overheating protection such as thermal switches that shut off power to overheated motors
- Personnel protection to prevent contact between people and hazardous parts of the electrical system
- Environmental protection controls for water levels, corrosive gases, liquids, explosive vapors, dusts, or lubricants
- Controls for regulating torque, acceleration, speed, or retarding functions of the motor
- Circuit protection of the conductors of the branch circuit in which the motor is connected.

FIGURE 13-40 In a synchronous motor, starting torque and motor speed can be regulated by passing three-phase rotor current through a resistor.

► Wrap-Up

Ready for Review

- ▶ By definition, motors are devices that take any form of energy, other than combustion, and convert it into mechanical energy.
- ▶ The widest classification of electric motors is according to the type of electrical current used: alternating current (AC) or direct current (DC).
- ▶ AC current has been used to power homes and industry since the 1890s.
- ▶ Single-phase current, also known as house current, is used to power lights and small appliances. It is called single phase because of the use of two wires, one neutral and one power, which provide a pathway for electricity flow between them.
- ▶ To improve the efficiency of devices using AC current, three-phase AC current can be used. Three-phase current provides more uniform delivery of current than single phase. Unlike single-phase current supplying AC using two wires, a neutral and a power wire, with perhaps a third ground wire for safety, three-phase current uses five wires. Three wires supply power; the other two are a neutral and often a ground wire.
- ▶ All AC motors typically consist of two basic parts. The first is an outside stationary component called a stator that uses coiled wire supplied with alternating current to produce a magnetic field. The second moving component, called the rotor, is attached to the output shaft. Rotors correspond to an armature in a DC motor.
- ▶ Close to 90% of induction motors use a squirrel cage-type rotor.
- ▶ Induction motors are the most commonly used type of AC motor.
- ▶ It is impossible for the rotor of an induction motor to turn at the same speed as the apparent rotating magnetic field of the stator. The difference between the speed of the rotating stator field and the rotor speed is called slip. The smaller the slip, the smaller the angle between the magnetic field and rotor conductor bars. Slip decreases the closer the rotor speed approaches the stator field speed.
- ▶ Single-phase motors will not operate from a stopped position unless they are provided some initial rotating force.
- ▶ The most common first type of split-phase induction motor is the capacitor-start type. Three components are used. One is a capacitor; the second is an additional winding called the starting or auxiliary winding; and the third is a switch, usually a centrifugal activated switch that closes when the motor stops and opens shortly after it starts.
- ▶ Another type of split-phase induction motor is the resistance-start motor. The difference is that the unbalance condition in the magnetic fields is produced by changing the resistance, or, more correctly, the impedance of the windings is unequal. The main winding has a low resistance in contrast to the start winding, which has high resistance.

- ▶ Three-phase squirrel cage induction motors are widely used as large industrial drive units because they are rugged, reliable, and economical. Three-phase motors are similar in operation and construction to single-phase motors except for the stator. Rather than use a single winding, a three phase motors uses three separate stator windings arranged with a 120-degree offset from one another.
- ▶ Synchronous motors are another category of AC motors; they are given the name “synchronous” because, unlike asynchronous induction motors, the rotor always attempts to line up its magnetic poles with the rotating magnetic field in the stator.
- ▶ The housings around a motor that support and protect components vary depending on the degree of protection required. Open-type enclosures are made from light-gauge sheet metal surrounding the stator, with end plates to support the shaft bearings and allow ventilation. A protected enclosure has no provisions for ventilation and is called drip-proof.

Key Terms

asynchronous motor A category of AC motors, also known as an induction motor where the rotor speed and apparent speed of the magnetic field in the stator winding are not synchronized. Asynchronous motors operating speed is always less than maximum speed.

auxiliary motor A motor that drives auxiliary devices using a belt or gear drive or that is directly coupled.

capacitor-start motor A motor using a capacitor in series with the starter winding to put the starter winding 90 degrees out of phase with the main winding. Capacitor-start systems are required to begin rotor movement.

centrifugal start switch Used by split-phase motors to place a starter winding in series with the main winding during initial motor start-up when no rotor speed is present.

counterelectromotive force (CEMF) Electric current induced in a winding caused by the collapse of an adjacent magnetic field.

delta-wound stators A three-phase stator wiring configuration where the stator windings are connected at each end to form a triangle resembling the Greek letter delta.

impedance An electrical term to describe resistance in an AC circuit.

induction motor The most common type of AC motor, where the rotor current flow is induced by the stator's moving magnetic field; also called asynchronous motors.

Lenz's law A law of electromagnetism stating that the current induced in a circuit due to a change or a motion in a magnetic field is so directed as to oppose the change in flux and to exert a mechanical force opposing the motion.

resistance-start motors A type of split-phase motor with a starter winding used to initiate rotor rotation. A resister placed

in series with the starter winding is used to unbalance motor magnetic fields to initiate rotor movement.

resolver A Hall-effect sensor used to measure the rotor position and speed for a motor controller in order to properly manage the motor operation in three-phase traction motors.

root mean square (RMS) A measurement method for AC voltage providing a comparable measurement of AC current to DC current. The RMS value of AC voltage refers to the effective value of AC voltage or current and not the wave peak positive-to-wave peak negative difference in voltage.

series-type hybrid electric drive A powertrain configuration where an engine drives only an electric generator, which in turn powers an electric motor.

single-phase current AC current that peaks two times during a cycle.

slip The difference between the speed of the rotating stator field and the rotor speed.

split-phase motor A single-phase motor with a starting winding used to initiate rotor movement.

squirrel cage rotor The type of construction used for rotors in an induction motor. In a squirrel cage rotor, the conductor bars are placed parallel to one another in a rotor cylinder. Ends of the conductor bar are connected with a shorting ring.

squirrel cage induction motor An AC motor with a rotor having solid conductor bars connected at each end with a shorting ring

synchronous motor A category of AC motors where the rotor and stator magnetic field revolve together at the same time.

traction motors Electric motors used in a propulsion drive system.

wye-wound stator A three-phase stator wiring configuration shaped like the letter “Y.” Each end of a stator’s three windings is connected to a neutral junction point. The other ends are connected to power leads.

Review Questions

- Which of the following motors is the most common type of AC motor used?
 - Synchronous
 - Spilt-phase
 - Capacitive-start
 - Induction
- Which of the following is true of a synchronous motor?
 - Requires some degree of rotor slip to rotate
 - Has a single layer of wire coils in the stator
 - Uses a wire wound rotor
 - Uses a squirrel cage-type rotor
- Which of the following features does an asynchronous motor use?
 - Only a single-phase stator winding
 - Slip rings to supply current to the rotor winding
 - A rotor speed matching the speed of the stator magnetic field
 - A rotor requiring some speed slip to rotate

- What determines the amount of slip needed by some AC electric motors?
 - The number of stator poles
 - The frequency of AC current
 - The load applied to the rotor
 - The angle of the magnetic fields
- How is the direction of motor rotation changed in a three-phase induction motor?
 - By changing the frequency of AC current
 - By installing a capacitor in series with one of the main windings
 - By installing a resister in series with one of the main windings
 - By switching two of the power conductor connections supplying the motor
- Which of the following motors uses a “run” capacitor?
 - Synchronous motors
 - Three-phase motors
 - Two-phase motors
 - Single-phase motors
- What is the likely explanation for a motor to start rotating after it is turned by hand?
 - A missing phase
 - A shorted stator winding
 - A defective rotor
 - A defective capacitor
- How many separate layers of stator windings are used by a single-phase motor?
 - Not enough information
 - One
 - Two
 - Three
- What is the primary advantage of using battery-operated electric equipment in underground mines?
 - The machines are less expensive to purchase.
 - Batteries last longer than engines.
 - Some ventilation shafts into the mine can be eliminated.
 - There is better traction.
- How do electric-drive machines reduce wear of brake friction material?
 - The traction motor is switched from motor to generator operation.
 - The electric motor is powered in a reverse direction.
 - The brakes charge on-board batteries.
 - Power is absorbed by AC–DC inverters.

ASE Technician A/Technician B Style Questions

- Technician A says that diesel engines will last longer between overhauls compared to the life cycle of an electric traction motor used in a mining machine. Technician B says that electric motors can last longer than diesel engines. Who is correct?
 - Technician A
 - Technician B

- c.** Both A and B
 - d.** Neither A nor B
- 2.** Technician A says that electric motors are more energy efficient than gasoline engines. Technician B says that diesel engines are more efficient than gasoline engines. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both A and B
 - d.** Neither A nor B
- 3.** Technician A says that single-phase motors are just as powerful as three-phase motors. Technician B says that three-phase AC hits peak voltage more times per second than single phase. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both A and B
 - d.** Neither A nor B
- 4.** Technician A says that the wire windings in the rotor of an asynchronous motor are replaceable. Technician B says that asynchronous motors do not use wire windings in the rotor. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both A and B
 - d.** Neither A nor B
- 5.** Technician A says that there is no such thing as two-phase electric current. Technician B says that an electric compressor motor is a two-phase motor and must be connected to two-phase current. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both A and B
 - d.** Neither A nor B
- 6.** Technician A says that DC motors used as auxiliary motors are more popular because they last longer. Technician B says that DC motors are more popular because they have fewer parts and are more simply designed. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both A and B
 - d.** Neither A nor B
- 7.** Technician A says that induction motor speed depends on the voltage powering the motor. Technician B says that single-phase motor speed depends on the amount of amperage the motor can handle. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both A and B
 - d.** Neither A nor B
- 8.** Technician A says that using AC current is more efficient than DC current because it can be transmitted farther with less voltage drop due to resistance. Technician B says using AC voltage is less efficient because its direction changes 60 times per second. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both A and B
 - d.** Neither A nor B
- 9.** While discussing possible causes for high voltage readings of 170 VAC at the connection to a single-phase motor, Technician A said that the voltmeter was not measuring AC current using the RMS method. Technician B said his meter was working properly and that the likely cause for the motor to burn out was 170 volts of single-phase current. Who is correct?
 - a.** Technician A
 - b.** Technician B

CHAPTER 14

Starting Systems

Knowledge Objectives

After reading this chapter, you will be able to:

- **KI4001** Identify and explain the function and operating principles of heavy-duty starting motors and circuits.
- **KI4002** Identify and describe the types of starter motors.
- **KI4003** Identify and describe the major components of a starting system.
- **KI4004** Identify and explain the purpose and function of starting system control components.
- **KI4005** Identify and describe the procedures for performing an on-machine starting system test.

Skills Objectives

After reading this chapter, you will be able to:

- **SI4001** Measure starter draw.
- **SI4002** Perform starter circuit cranking voltage and voltage drop tests; determine needed action.
- **SI4003** Inspect and test components (key switch, push button, and/or magnetic switch) and wires and harnesses in the starter control circuit; replace as needed.
- **SI4004** Inspect and test starter relays and solenoids/switches; replace as needed.
- **SI4005** Remove and replace a starter motor and inspect the ring gear or flexplate.
- **SI4006** Overhaul a starter motor.

► Introduction

Dozens of electric motors are found in mobile off-road equipment operating a variety of devices, from electric seats to fuel and coolant pumps, to fan blower motors and even instrument gauges. The largest of all these electric motors is the starter motor, like the one shown in **FIGURE 14-1**.

The starting system provides a method of rotating (cranking) the mobile off-road equipment's internal combustion engine (ICE) to begin the combustion cycle. The starter is designed to work for short periods of time and must crank the engine at sufficient speed for it to start. Modern starting systems are very effective provided that they are well maintained.

Understanding and maintaining starting systems is important because diagnosing “no-start” conditions is costly in terms of machine downtime and component costs if they are “over repaired” or haphazardly investigated. In fact, various manufacturers have noted that between 55% and 80% of all starters returned for warranty were not defective. Equipment and operator safety can be jeopardized if the starting system is not properly repaired and maintained. Interlocked circuits,

FIGURE 14-1 Typical starter motor cross section.

which prevent the engine from starting under various operating conditions, and the high current supplied by multiple starting batteries are just two of the safety concerns with this system.

► Fundamentals of Starting Systems and Circuits

K14001

The starting/cranking system consists of the battery, high- and low-amperage cables, a solenoid, a starter motor assembly ring gear, and the ignition switch. On ECM-controlled starting systems, the ECM enables the operation of a relay to energize the starter circuit. Data supplied by other on-board network modules, along with control algorithms in the module, determine when and for how long the starter will crank. A control circuit determines when and if the cranking circuit will function.

During the cranking process, two actions occur. The pinion of the starter motor engages with the flywheel ring gear, and the starter motor then rotates to turn over, or crank, the engine. The starter motor is an electric motor mounted on the engine block or transmission. It is typically powered by a 12- or 24-volt battery and is designed to have high rotational torque at low speeds. The starter cables are the heaviest conductors in the machine because they carry the high current needed by the starter motor. The starter motor causes the engine flywheel and crankshaft to rotate from a resting position and keeps them turning until the engine fires and runs on its own.

High-compression-ratio diesel engines with large displacements require high amounts of electrical current, so multiple batteries are connected together to supply either more amperage or voltage. To supply more cranking amperage in a 12-volt system, batteries are connected in parallel. Adding more batteries connected in parallel increases the amount of amperage available for cranking, but the system voltage remains the same. Connecting batteries in series increases available voltage, but amperage supplied to the starter remains the same.

You Are the Mobile Heavy Equipment Technician

The cost of a no-start condition in the equipment you maintain is extraordinarily high. Equipment productivity, labor hours, and operator time are all lost. In addition, customer aggravation increases, as does the expense of resolving no-start conditions. At the specific direction from management to end or dramatically reduce the number of no-start complaints, you begin to analyze some of the common root causes of the starting system failures. Reviewing service records for the repaired equipment, you discover that the starting motors are frequently burned out, and cable terminals are loose and often burned as well. You also notice that there doesn't seem to be a specific preventative maintenance schedule in place to evaluate the condition of the starting system. It is only when the equipment does not start that the problems are identified, but that occurs too late to prevent disruption of operations. As you consider what steps to take to prevent the no-start complaints, answer the following questions.

1. Explain how the conditions that cause low-voltage burnout actually damage starting motors and starting-motor connections.
2. What maintenance practices would you recommend to prevent low-voltage burnout of starting motors and connections?
3. What trend would you observe regarding the voltage and amperage measurements made during a starter draw test if a starter were beginning to fail due to burnt brushes, armature, and field windings?

Demands on Today's Starting Systems

Today's off-road mobile equipment engines demand the most from starter motors because emission reduction strategies have increased engine cylinder pressures during cranking. Idle reduction policies require starters to more frequently crank warm engines, which are more mechanically resistive.

In spite of the increasing demands, new designs of starter motors and systems controls are enabling starters to last longer and increase output torque while substantially reducing motor weight. A typical example of this is the improvements and changes that have occurred to Delco Remy™ starter motors in recent times. The Delco Remy TM 40MT (**FIGURE 14-2A**) weighs 66 lb (30 kg), and the 37MT weighs only 30 lb (14 kg) yet produces more cranking torque with much greater reliability (**FIGURE 14-2B**). The 37MT is the latest, third-generation starter using a gear reduction drive system to multiply torque output. The 39MT, also a direct drive type starter like the 40MT, weighs approximately 50 lb (23 kg). All three starters are used on engines from 10 to 15L displacement (**FIGURE 14-2C**). Minimum life expectancy for a starter now is 4 years, with 7,000 start cycles.

Most starting systems have only a single starter motor to crank the engine. In large displacement engines, such as locomotive diesel engines, where the starting demands are higher, two starter motors may be required to crank the engine over.

Starter Motor Classification

Electric starter motors were first installed in the 1912 Cadillac cars to replace hand-operated engine cranks. Although electric motors were invented decades before this, the concept that made electric starters practical was the idea of building motors to operate at high-ampere levels for a few seconds and not burn out. The Dayton Electric Company, later shortened and called DELCO™, pioneered the use of high-current-draw motors that enabled the starter to develop a tremendous amount of torque. The motors were unlike any compact electric motors of the day, which were all designed for continuous operation.

Using a small pinion gear, the starter motor rotates the engine through a ring gear attached to the flywheel. When the starter motor begins to turn, the pinion teeth quickly line up with the flywheel teeth and rotate the engine at a minimum of 125 rpm for a four-stroke diesel engine to an average of 200–250 rpm. In gasoline engines, the ratio between the flywheel ring gear and pinion gear is anywhere between 10 and 15:1. Diesel engines use 18:1 to 25:1, with 20:1 being most common.

Currently, there are three major categories of electric starters used in mobile off-road equipment.

- **Direct drive:** The motor armature directly engages the flywheel through a pinion gear. In this arrangement (**FIGURE 14-3**), the only gear torque multiplication is between the pinion gear and the ring gear.
- **Reduction gear drive:** The motor multiplies torque to the starter pinion gear by using an extra gear between the armature and the starter drive mechanism. The gear reduction allows the starter to spin at a higher speed with lower

FIGURE 14-2 Three generations of improvements in Delco starters. **A.** First-generation Delco 40MT. **B.** Second-generation Delco 39MT. **C.** Third-generation Delco 37MT.

current while still creating the required torque through the reduction gear to crank the engine. The reduction drive of this type of starter motor is approximately between 3.3:1 and 5.7:1. These types of starters (**FIGURE 14-4**) can be identified by an offset drive housing to the motor housing.

FIGURE 14-3 A typical direct-drive starter motor.

FIGURE 14-4 A typical reduction drive starter motor.

- **Planetary gear reduction drive:** Another type of gear reduction system, the planetary gear system (**FIGURE 14-5**), reduces the starter profile using a planetary gear set rather than a spur-type gears to multiply motor torque to the pinion gear. Gear reduction starters can reduce starter weight by more than 50%.

Direct-drive starters are becoming less common due to their larger size, heavier weight, and higher current requirements. The use of gear reduction and planetary gear reduction starter

designs means the motor requires less current, is more compact, and is lighter—while increasing cranking torque. Higher motor speeds used in these units result in potentially less motor damage than direct-drive units because less current is needed to produce torque. The disadvantage of the smaller starter profile in comparison to direct-drive starters is the inability to tolerate high heat loads caused by prolonged engine cranking.

Pneumatic, or air, starters (**FIGURE 14-6**), are another type of starter motor used on some diesel engines. Without the need for batteries, air starting systems are lighter weight, and crank engines at faster speeds than electric starters can. Engines requiring higher cranking speeds, such as two-stroke Detroit Diesels, benefit from the use of air starters. Because air starters do not rely on batteries, high torque output in cold weather operation is instantly available.

The system consists of a geared air motor, starting valve, and a pressure tank. Compressed air from a dedicated reservoir tank is used to spin the motor after the operator pushes a spring-loaded, dash-mounted air valve. A set of reduction gears between the motor and pinion gears multiplies motor torque while engaging the flywheel ring gear. Once running, the engine recharges a dedicated starter air reservoir.

Hydraulic starting systems are another type of starter used on some diesel engines. They can be used to start engines up to

FIGURE 14-5 A typical planetary gear reduction drive starter motor.

FIGURE 14-6 A typical air starter.

80 liters in size. Hydraulic starters are most common in underground mining applications, offshore platforms, and other hazardous locations where it is important to reduce the risk of fire hazards. Like air starters, they are capable of higher cranking speeds and do not have electrical connections, which are prone to corrosion.

DC Motor Principles

All electric motors operate using principles of magnetic attraction and repulsion. Because like magnetic poles repel

one another and unlike poles attract, it is possible to arrange magnetic poles within the motor to be continuously in a state of repulsion and attraction, which produces the motor action.

The magnetic fields are produced either by permanent magnets or electromagnets, which use coils or loops of conductors with electric current flowing through them to create magnetic fields. Two magnetic fields are required for motor action: one surrounds the motor armature and is called the field winding, and the other is in the rotating armature, as illustrated in **FIGURE 14-7**.

The magnetic field in the field is produced by permanent magnets, but in all heavy-duty applications by strong electromagnets. The armature's magnetic field is generated in loops of wire that form the armature windings. Motor action occurs through the interaction of the magnetic fields of the field coils and the armature, which causes a rotational force to act on the armature, producing the turning motion.

Heavy-duty starter motors use electromagnets in the field and armature windings, which are intensified by the low-reluctance, laminated, iron armature shaft and soft iron starter case. Motors used for smaller applications, such as blower and wiper motors, may use permanent magnets for the field and electromagnets for the armature. Permanent magnets used to replace electromagnets in the motor field are not used in medium or heavy-duty diesel engine starter applications.

FIGURE 14-7 Basic direct-current electric motor operation. Two magnetic fields are required for motor action, one in the field and the other in the armature.

► Types of DC Motors

K14002

Direct current motors are categorized by the arrangement of electromagnetic circuits producing magnetic forces of repulsion and attraction. Common electric motor classification used in mobile off-road equipment is as follows:

- **Series:** Field and armature windings are connected in series. These motors develop the highest torque and are used as starting motors.
- **Shunt (parallel wound):** Field and armature windings are connected in parallel. These motors develop less torque but maintain a constant speed. They are often used as blower motors.
- **Compound:** Field and armature windings have both series and parallel connections. The motor has good starting torque and stable operating speed. These motors are commonly used in wipers and power seats.
- **Stepper:** The field is made from an electromagnet, and the armature has two or more coils that are energized by a microcontroller. These motors are used in instrument clusters gauges, actuators for turbochargers, and EGR valves, where high-precision movement is required.

Series Motors

The series and shunt motor are the two most common types found in the off-road industry. **FIGURE 14-8** shows the current flow circuits through a series and shunt motor.

Note the difference in the way the current flows through the fields. Series motors are called “series” because the field and armature windings are connected in series. So, current flows through the field windings first and then to the armature windings before leaving the armature through the positive

FIGURE 14-8 Typical circuits for basic series and shunt motors.

brush. This means current first passes from the negative chassis ground, through a brush, and into the armature. Current leaves from another brush and passes into the field coils before returning to the battery positive. Because it is a series circuit,

FIGURE 14-9 Comparing amperage drawn, speed, and torque of series and shunt motors.

any unwanted resistance inside the motor, whether it is a burnt contact or loose brush, will reduce current flow throughout the entire motor circuit.

Series-wound motors are primarily used in starter motors because they develop the greatest amount of torque at zero rpm, which is ideal for developing breakaway torque needed to crank a stopped engine. As magnetic field strength is always proportional to amperage and not voltage, the initial amperage drawn by a series motor produces the most torque. In comparison, shunt motors produce less torque than series motors but do not drop as much speed as torque requirements diminish. This makes them ideal for applications like blower motors (**FIGURE 14-9**).

Series Motor Current Flow

The current flow for a series motor (**FIGURE 14-10**) is as follows:

1. Current first enters the motor through the brush connected to negative chassis ground. Current passes through the armature via the commutator and leaves through the second brush connected to the field winding. A magnetic field is created in the armature.
2. Current passes through the windings of the field coils. The laminated iron making up the pole shoes intensifies the magnetic field strength. The direction the winding is wound around the pole shoe establishes the polarity of the pole shoe. The field windings are wound in directions opposite to one another to produce a like pole to the armatures, which always opposes the magnetic pole produced in the armature.

FIGURE 14-10 Current flow in a series motor and through the armature and fields in series.

3. The forces of repulsion between the field coil and armature cause the armature to turn.
4. Each armature winding is connected to a pair of segments on the commutator. The commutator turns with the armature, causing the stationary brushes to continuously connect with a new armature winding as the armature rotates. This arrangement enables the forces of repulsion to constantly reposition to maintain starter motor rotation.

Series Motor Operational Characteristics

Series wound motors also are self-limiting in speed due to the development of a **counter-electromotive force (CEMF)**. CEMF is produced by the spinning magnetic field of the armature, which induces electrical current flow in the opposite direction of battery current passing through the motor. Battery current and CEMF current both flow through a motor at the same time, but in opposite directions, which means CEMF provides resistance to battery current flow. It is important to observe that the faster the motor turns, the greater the CEMF, resulting in less current drawn from the battery. Higher voltage from cranking batteries produces greater motor speed and more CEMF. **FIGURE 14-11** illustrates the relationship between motor speed, torque, and amperage draw.

Consider the following relationship between armature speed, CEMF, amperage, and torque for a series starter motor:

- The faster the armature spins, the greater the CEMF current induced in the opposite direction of battery current flow.
- The starter draws less current from the battery as it spins faster due to CEMF resistance.
- Because less current is used at higher speeds, magnetic fields will weaken, and starter torque drops off.
- Slower motor speeds mean less CEMF resistance to battery current flow through the starter and results in higher battery amperage drawn by the starter.
- Greatest torque is produced at low speed because the motor will draw the highest amperage.

► TECHNICIAN TIP

Weak and discharged batteries are a starting motor's worst enemy because they can cause low-voltage burnout. Low battery voltage prevents the starter from spinning as fast as it should, which reduces CEMF—a

FIGURE 14-11 As motor speed increases, more CEMF is produced.

starter's internal resistance when operating. With lower internal resistance, the starter draws more amperage than it should, which leads to heat damage to starter windings, solenoids, and external circuits.

Amperage drawn by a starter at normal room temperature with a fully charged battery ranges from an average of 350 amps for a 7-liter engine to 800 or 900 amps for a 15-liter engine. Initial starting amperage is much higher because the engine is stopped and requires more torque from the starting motor to accelerate the engine from 0 rpm to cranking speed. Because of the high amperage drawn during cranking, the starter can only operate for short periods of time before cooling. Heat produced by continuous operation for any length of time will cause serious damage to the motor. Connections become loose and burnt. Some will even melt. Brushes and insulation will become burned, as well as motor windings. To help prevent heat damage, armature windings are brazed rather than soldered to the commutator. The starter must never operate for more than 30 seconds at a time and should rest for 2 minutes between extended crank cycles. This permits the heat to dissipate without causing damage to the starting motor.

Low-Voltage Burnout

Cranking an engine with low battery voltage causes one of the most damaging conditions for a starter. **Low-voltage burnout** occurs when excess amperage flows through the starter, causing the motor to burn out prematurely. When battery voltage is low, the starter will use even more amperage to rotate. This happens because starters are constant power devices. That is, starters will use any combination of voltage and amperage to produce the necessary output power, rated in watts. For example, if 7,200 watts of power is needed to operate a starter at 24 volts, 300 amps are required. If available battery voltage fell to 18 volts, then 400 amps would be needed according to Watts's law ($\text{watts} = \text{volts} \times \text{amperage}$). Increasing amperage drawn from batteries, in turn, increases batteries' internal resistance. Increased circuit resistance through the battery causes available voltage to drop even further, which in turn increases the amperage needed to rotate the starter. Slower starter rotation means less CEMF is developed. Consequently, amperage through the starter climbs even

more. To prevent damage from low voltage to the starter, cables, solenoid, and switches, several design and maintenance practices are required.

- **Correct battery sizing:** Batteries must be sized according to their CCA to maintain a cranking voltage of no less than 10.5 volts (for 12-volt systems) or 18 volts (for a 24-volt system) after three consecutive cranking periods lasting 30 seconds. The appropriate 2-minute cooling period is included in this estimation.
- **Correct sizing of battery cables:** Dedicated battery negative and positive cables are needed for heavier starting systems. Cable diameters should be sized for maximum amperage capacity using OEM recommendations. Double cables are needed when using four or more starting batteries.
- **Using over-crank protection switches.** Thermal protection switches may be located in the starter housing and connected in series with the starter solenoid ground circuit. When hot, the switch opens and prevents the starter solenoid from operating until the starter is sufficiently cooled.
- **Using voltage-sensitive starter control circuit relays:** Starter relays are produced that will disengage when battery voltage falls below a predetermined level, thus disconnecting the starter circuit. Alternatively, an electronic control module (ECM), which supplies current to energize the starter, can monitor battery voltage, enabling the ECM to disconnect the starter relay when battery current falls too low during cranking. Disconnect voltage is approximately 7.2 volts (12-volt system) or 14.4 volts (24-volt system).
- **Using ultracapacitors:** Ultracapacitors are a recent application of organic capacitors used to provide cranking assist to HD starters. Up to 1,800 amps of current can rapidly discharge for a brief moment to provide battery assist to the starting motor. As illustrated in **FIGURE 14-12**, ultracapacitors connected in parallel to the battery provide a high initial current to the starter to speed up the armature rotation. Supplementing the available amperage to the starter during the initial cranking period reduces the likelihood of a low-voltage burnout due to low CEMF when armature speed is reduced.

► TECHNICIAN TIP

Battery capacity is specifically designed to meet the cranking requirements of the engine. An under-capacity set of batteries will *not* be capable of delivering the required current flow to the starter motor while still maintaining sufficient battery voltage. The batteries may cause low-voltage burnout of the starter and damage the starter circuit. It may also create a situation where there is insufficient voltage available to operate the engine's ECM during cranking. Although not as common a problem, excessive battery capacity can also damage the starter motor by supplying too much amperage while cranking. This can create a situation in which excessive torque is produced from the starter motor, damaging the starter drive and ring gear.

FIGURE 14-12 Power assist from ultracapacitors reduces the likelihood of low-voltage burnout.

► Components of Starters

KI 4003

Regardless of the motor design, a starter motor consists of housing, field coils, an armature, a commutator, brushes, end frames, and a solenoid-operated shift mechanism. Major variations between starters are in the starter drive mechanism. Some starters use a gear-reduction drive, whereas others use a direct-drive configuration. Still other starter motors, called axial starter motors, are a type of direct-drive starter. Axial starter motors use an axial sliding armature to engage the pinion with the fly-wheel. This type of starter is discussed later in this chapter.

Starter Housing and Field Coils

The starter housing, or frame, encloses and supports the internal starter components, protecting them and intensifying the magnetic fields produced in the field coils. Housings and pole shoes are made from soft iron, which conducts magnetic fields with less resistance than air or other materials, which concentrates the magnetic field produced in the fields, making a more powerful magnet. In the starter housing shown in **FIGURE 14-13**, field coils and their pole shoes are securely attached to the inside of the iron housing.

The field coils are insulated from the housing and are connected to a terminal, called the motor terminal, which protrudes through to the housing. Fields will have a north or south magnetic polarity facing inward or outward depending on the direction of current flow. The magnetic flux of the pole shoes is illustrated in **FIGURE 14-14**.

Field coils are connected in series with the armature windings through the starter brushes. In a four-brush starter motor,

FIGURE 14-13 A set of starter motor fields, windings, and housing.

two brushes are used to connect the field coils to the armature and the other two brushes connect to ground to complete the series circuit.

Armature

The **armature** is the only rotating component of the starter. Armatures (**FIGURE 14-15**) have three main components: the shaft, windings, and the commutator.

Armature Shaft and Windings

Different from the thin wire used in shunt motors, armature windings are made of heavy, flat, copper strips that can handle the heavy current flow of the series motor. The windings are made of numerous coils of a single loop each. The sides of

FIGURE 14-14 Field coils are wound around pole shoes, producing a north and south magnetic field.

FIGURE 14-15 Features of an armature.

these loops fit into slots in the armature core or shaft, but they are insulated from it with insulating strips and varnish applied to the winding before placement. Each slot contains the side of one-half of a coil and is connected to a commutator segment. In a four-brush motor, the halves of a coil are wound at 90 degrees to each other. The coils connect to each other at the commutator so that current flows through all of the armature windings at the same time. This arrangement generates a magnetic field around each armature winding. The interaction between the armature and field windings' magnetic fields produces a torque or twisting force that turns the armature.

Commutator and Commutation

The commutator assembly is pressed onto the armature shaft. It is made up of heavy copper segments separated from each other and the armature shaft by insulation. The commutator segments connect to the ends of the armature windings. Starter motors have four or more brushes that ride on the commutator segments and carry the heavy current flow from the stationary field coils to the rotating armature windings via the commutator segments. A brush holder holds the brushes in position.

The commutator's role is to switch the direction of current flow through each armature coil as the armature rotates, thereby maintaining the rotary movement by ensuring the magnetic pole in the field winding is always the same as the pole in the armature winding opposite it. For a simple explanation of how a commutator works, consider a basic motor with a single loop of wire. When current flows in a conductor, an electromagnetic field is generated around it. If the conductor is placed in a stationary electromagnetic field with current flowing through the field in the opposite direction, the two magnetic fields will oppose one another, and the conductor will be repelled or pushed away from the stationary field. Reversing the direction of current flow in the conductor will cause the conductor to move in the opposite direction. This is known as the motor effect and is greatest when the current-carrying conductor and the stationary magnetic field are at right angles to each other.

By switching the direction of current flow through the conductor at the right time, the conductor can be continuously pushed away from one field winding and pulled toward another (**FIGURE 14-16**).

The turning motion is called the motor effect and causes the loop to rotate until it is at 90 degrees to the magnetic field. To continue rotation, the direction of current flow in the conductor must be reversed. A commutator is used to continually reverse the current flow to maintain rotation of the loop (**FIGURE 14-17**).

For example, a commutator consists of two semicircular segments that are connected to the two ends of the loop and are insulated from each other. Carbon brushes provide a sliding connection to the commutator to complete the circuit and allow current to flow through the loop. This continuously changing direction of current through the loop maintains a consistent direction of rotation of the loop. To achieve a uniform motion and torque output, the number of loops must be increased. The

FIGURE 14-16 Simple single-loop motor and electromagnetic fields with commutator and brushes.

FIGURE 14-17 Simple single-loop motor and electromagnetic fields at the switching point of the commutator.

additional loops smooth out the rotational forces. A starter motor armature has a large number of conductor loops and therefore has many segments on the commutator. A simple multi-loop motor is depicted in **FIGURE 14-18**.

Solenoid and Shift Mechanism

The solenoid on the starter motor performs two main functions:

1. It switches on and off the high current flow required by the starter motor.
2. It engages the starter drive with the ring gear.

The solenoid-operated shift mechanism is mounted in a case that is sealed to keep out oil and road splash (**FIGURE 14-19**).

In direct-drive starters, the case is flange mounted to the starter motor case and contains two electromagnets around a hollow core. A movable iron plunger is installed in the hollow core. Energizing the electromagnets pulls the iron plunger, which in turn moves a shift lever, engaging the drive pinion gear (**FIGURE 14-20**).

At the same time, moving the iron core also closes a set of contacts to connect battery current with the motor terminal, directing full battery current to the field coils and starter

FIGURE 14-18 Simple multi-loop motor and electromagnetic fields with commutator and brushes.

FIGURE 14-19 The solenoid uses two electrical windings. **A.** A hold-in winding. **B.** A pull-in winding.

motor armature for cranking power. The starter pinion gear engages the flywheel ring gear before energizing the motor terminal to prevent damage to either gear from spinning teeth (Figure 14-20).

FIGURE 14-20 Solenoid starter contacts and starter drive linkage.

► TECHNICIAN TIP

A solenoid is an electromagnetic device that is used to perform work and has mechanical action. A solenoid is made with one or two coil windings wound around an iron tube. When electrical current is passed through the coil windings, it creates electromagnetic force that creates linear action, pushing or pulling an iron core. When the core is connected to a lever or other mechanical device, the solenoid can put this mechanical movement to practical use. For example, it may engage the pinion of the starter motor with the flywheel; shift gears in electronically controlled transmissions; shut off air, fuel, or oil supplies; engage engine and exhaust brakes; move the fuel rack in a diesel engine; and so on. Solenoids can also close contacts, such as the solenoid contact in a starter motor solenoid.

► TECHNICIAN TIP

Low battery voltage produces starter chatter—the rapid cycling of the solenoid plunger in and out of engagement. This happens because the thinner windings of the hold-in circuit are more sensitive to voltage drop

than pull-in windings. When the solenoid closes the connection between the battery and motor terminal, the available voltage also drops due to the increased amperage flow from the battery.

Starter Drive Mechanisms

The starter drive transmits the rotational force from the starter armature to the engine via the ring gear that is mounted on the engine flywheel or torque converter. Armature rotation is transferred to the pinion gear through a variety of mechanisms.

Direct-drive starters, which diesel engines used exclusively for many decades, transferred torque directly to the pinion gear. Today, gear reduction starters using both planetary and spur-gear mechanisms have replaced direct drives. With a solenoid-actuated, direct-drive starting system, teeth on the pinion gear do not immediately mesh with the flywheel ring gear. If this occurs, a spring located behind the pinion gear compresses so that the solenoid plunger can complete its stroke. When the starter motor armature begins to turn, the pinion teeth quickly line up with the flywheel teeth, and the spring pressure helps them to mesh (**FIGURE 14-21**).

The pinion drive gear is attached to a roller-type, one-way (or overrunning) clutch that is splined to the starter armature, as in **FIGURE 14-22**.

FIGURE 14-21 Both windings are energized, and the solenoid plunger is starting to move toward the cap.

FIGURE 14-22 Starter drive one-way clutch.

A one-way clutch is in all pinion gears and operates like a ratchet to protect the starter motor. It drives when turned in one direction and slips when turned in the opposite direction. When the engine starts and runs, the starter motor would be damaged if it remained connected to the engine through the flywheel. The ring gear-to-pinion gear ratio, which multiplies starter torque, also multiplies the starter's speed when driven by the engine. At idle, with a 20:1 gear ratio, the starter's armature will turn 14,000 rpm or more, which will destroy the armature windings. To prevent this, the one-way overrunning clutch allows the pinion gear to spin—but not turn the armature if it remains or is accidentally engaged with the flywheel. When the solenoid is de-energized, the shift assembly is pulled away from the flywheel through spring pressure (**FIGURE 14-23**).

Most starters have a pinion clearance adjustment to ensure the pinion engages fully with the flywheel while maintaining a clearance from the drive end housing. Starter motors usually use one of the following three methods for providing pinion clearance adjustment, as illustrated in **FIGURE 14-24**. Proper adjustment of the mechanism is important to prevent damage to the flywheel teeth.

- An eccentric shift fork pin, which is turned until the correct pinion clearance is measured, and then locked off by a lock nut
- Shims, which are placed between the solenoid and housing to adjust pinion clearance
- A screw or nut on the solenoid core where it connects to the shift fork; tightening and loosening the screw or nut adjusts pinion clearance

► Starter Control Circuits

K14004

The starter control circuit, in its most basic form, has an ignition switch directly controlling the starter solenoid to operate the starter motor. In modern machines, the circuits are more

FIGURE 14-23 Ring gear damage can result from poorly adjusted pinion clearance or engagement of the pinion while the ring gear is rotating.

FIGURE 14-24 Typical methods of adjusting pinion clearance.

complex, as relays and control circuits, such as transmission neutral and clutch switches, are added to improve reliability and safety. The latest models of mobile off-road equipment use an electrical system control module, which interfaces with the machines on-board network that receives data from various sensors, to control the operation of the starter control circuit.

Solenoid Control Relay

Because it is neither practical nor safe to have large battery and starter cables routed in the cab of a machine, the starter control circuit allows the operator to use a small amount of battery current provided by the ignition switch to control the flow of a large amount of current in the starting circuit. The control circuit may also have a provision for locking out the starter engagement if the engine is running or the starter has overheated. Safety switches, also called neutral safety switches (**FIGURE 14-25A**), can be located in either of two places in the control circuit—interrupting either the ground or battery positive of the starter relay (**FIGURE 14-25B**). Placing the transmission in Park or Neutral, or depressing the clutch, closes the starter control circuit so current can flow to the relay switch. The safety switch can also be connected between the relay switch and its ground so that the switch must be closed before current can flow from the magnetic switch to ground.

ECM-controlled circuits use the ignition key as an input device and control the starter operation by supplying a ground to the starter relay. The starter relay is the point in the starting system where the control circuit and starter solenoid circuit join. Because starter solenoids can consume between 30 and 60 amps, relays are needed to switch low current from the ignition switch or starter button to energize the starter solenoid circuit. Starter relays are a type of intermittent duty relay. This means they are not intended for continuous operation or operation longer than a minute. The intermittent duty relay has heavy, large-gauge windings in the control circuit, capable

of producing strong magnetic fields, which are less sensitive to voltage drop during cranking.

As there is a relatively high amount of amperage drawn by the starter solenoid itself, solenoid circuits have a minimum of one relay to switch current flow to the solenoid circuit. The relay may be controlled by a separate push button located in the dash or by an ignition key switch. On electronically controlled engines, it is more common to have the circuit controlled by a start button than the key switch. Having a start button prevents voltage drops through the switch. Likewise, a start button also prevents voltage spikes from the magnetic field collapse of the relay's coil, which could travel back to other ignition circuits through the key (**FIGURE 14-26**).

The ignition switch has other jobs besides controlling the starting circuit. The ignition switch normally has at least four separate positions: Accessory, Off, On (Run), and Start. There may be a separate position for “proving out,” which test illuminates on-dash lights and gauges. When a machine has a push-button starter switch, battery voltage is available to the button switch only when the ignition switch is in the On position. When the starter pushbutton is pushed, current flows through the control circuit to the starter relay.

Relays use electromagnets to close contacts and act like a switch. Larger relays are sometimes referred to as “mag” switches.

Over-crank Protection (OCP)

Some starter motors are equipped with an **over-crank protection (OCP) thermostat**. The thermostat monitors the temperature of the motor (**FIGURE 14-27**).

If prolonged cranking causes the motor temperature to exceed a safe threshold, the thermostat will open the relay circuit, and the current to the solenoid is interrupted.

ADLO Lockout

Another device that may be used within the starter control circuit is **automatic disengagement lockout (ADLO)** (**FIGURE 14-28**).

FIGURE 14-25 Basic starter control circuit. **A.** Neutral safety switch circuit. **B.** Clutch switch circuit.

The ADLO circuit prevents the starter motor from operating if the engine is running. It does this by using a **frequency-sensing relay** connected to the alternator, which detects AC current only when the alternator is charging. The ADLO relay contacts are connected in series in the starter motor control circuit. If the engine is running, the relay prevents starter engagement and disengages the starter if the key switch is left engaged too long after the engine starts.

Voltage-Sensing Relay

Because starters can be damaged from low battery voltage, some companies find the solution is to prevent the starter from cranking when the battery voltage is too low. This also has the additional benefit of preventing prolonged cranking. The voltage-sensing relay is connected in series to the solenoid control circuit. When the battery voltage drops below 7.2 volts

FIGURE 14-26 A relay prevents high-voltage spikes produced through self-induction in the solenoid from damaging the electrical system.

FIGURE 14-27 A thermostat switch monitors starter temperature and opens the starter circuit if the starter motor overheats.

while cranking, the voltage-sensing relay will typically open-circuit the starter relay circuit (**FIGURE 14-29**).

► Starting System Testing

K14005

The starting system requires testing when the engine will not crank, cranks slowly, cranks intermittently, or when the starter motor will not turn. Various manufacturers report that between 55% and 80% of defective starters returned for warranty work normally when tested. That points to poor or incomplete diagnosis of the starting and related systems and circuits. The starting system is just part of the overall machine's electrical and mechanical system. As such, there are areas of overlap between the various electrical and mechanical systems on the machine. For example, the starter system makes use of the batteries to supply power for starting, but the charging system has to

FIGURE 14-28 The ADLO relay senses alternator frequency and prevents the starter motor from operating while the engine is running.

FIGURE 14-29 A low voltage-sensing relay can be connected in series with the starter control circuit to prevent the starter motor from operating if a low-battery-voltage condition occurs.

provide an adequate charge to ensure there is enough power to start the engine. At the same time, the engine's mechanical condition affects the load on the starter motor. So, when testing the starting system, also bear in mind that other electrical systems and mechanical items may require inspection to ensure a successful repair.

Because cranking torque produced from a starting motor is also affected by the condition and charge of the battery, the condition of the battery has to be qualified first before performing starting systems checks. Battery checks include the following:

- Verifying the battery voltage matches the voltage rating of the starter motor
- Ensuring that cranking amperage (CA or CCA) of the batteries meets or exceeds OEM recommendations
- Verifying that the state of charge is not lower than 50% and that open-circuit voltage is not less than 12.4 volts or 24.8 volts
- Measuring the batteries' capacity through load testing or conductance testing

For information on how to undertake battery checks, review the Servicing Batteries chapter.

► TECHNICIAN TIP

Low battery voltage and weak batteries are the primary cause of stress to starters and of excessive starter amperage draw. Faulty batteries also stress charging circuits, as an alternator is forced to continually charge a weak battery. Liquid starting aids can also produce engine "kickback" and apply extreme twisting forces to the motor. Heat from over-cranking and vibration from loose mountings are other leading causes of starter damage (**FIGURE 14-30**).

FIGURE 14-30 A burned solenoid contact disc caused by low available voltage.

Differentiating Between Electrical and Mechanical Problems

Whether a slow-crank or a no-crank condition, failure to crank over properly can be caused by electrical or mechanical problems. For example, slow cranking could result from an electrical fault such as high resistance in the solenoid contacts. This problem could be resolved by replacing the starter with a new or remanufactured unit. But the slow-crank condition could also be caused by a mechanical engine fault such as a spun main bearing that is causing a lot of drag on the crankshaft and preventing the starter from cranking it over at normal speed. In this case, the entire engine will have to be rebuilt.

As you can imagine, telling customers that they need a new starter motor when in fact they need a new engine (costing 10–20 times as much money) will not make them very happy with you. It is important to be able to differentiate between the two types of faults so that a wrong diagnosis can be avoided and the problem fixed appropriately the first time. Typical electrical problems that can cause starting system problems include loose, dirty, or corroded terminals and connectors; a discharged or faulty battery; a faulty starter motor; or a faulty control circuit.

Mechanical problems that may cause starting system problems include seized pistons or bearings, hydrostatic lock from liquid in the cylinder(s) (for example, a leaky fuel pressure regulator or water ingestion during off-road operation), incorrect injection or valve timing, a seized alternator or other belt-driven device, and so on. Gathering as much customer and equipment information as possible will assist in narrowing down the possible causes of the fault.

A slow-crank condition accompanied by a high draw could be due to a fault in the starter or to engine mechanical fault. If a mechanical fault is suspected, check the oil and coolant for signs of contamination. If the coolant and oil are mixing, suspect a head gasket or cracked head/block issue. If the oil and coolant are not contaminated, turn the engine over by hand to see if it is tight compared with a similar engine that is known to be good. If it is harder to turn than it should be, remove the accessory drive belt, spin each of the accessories, and try to turn the engine over again. If it is still hard to turn over, you will have to go deeper in your visual inspection and start disassembling components based on the information you have gathered along the way. For example, if the crankshaft cannot be turned a complete revolution, remove the injectors and see if liquid is ejected out of one or more cylinders. If so, the engine was hydrolocked, and you need to determine the cause. If no liquids are ejected, then you need to disassemble the engine further until you determine the cause of the mechanical resistance.

The important thing to remember is that slow-crank and no-crank conditions can be caused by both electrical and mechanical faults, so do not jump to conclusions. You need to identify the root cause of the fault through tests so that you can advise the customer on what is needed to repair the machine.

Starter Motor Tests

The inspection and measurement procedures used to diagnose starting system complaints should be symptom based. That is, a flow chart should be used to begin a proper sequence of pin-point checks recommended by the OEM. Symptoms include intermittent and no start, slow cranking, prolonged cranking, starter chatter, and starter noise. Any diagnostic procedure should begin with qualifying the condition of the batteries and inspecting all battery cables, grounds, and connections. Information on how to undertake battery checks can be found in the Servicing Batteries chapter.

Listed here are some of the faults that may occur within the starter motor:

- Worn brushes: Intermittent starter operation or starter operation that resumes after it is tapped with a hammer

indicates brushes with poor commutator contact. Poor contact could be due to weak spring tension after a brush wears out. Poor brush contact with the commutator can also be caused by loss of brush spring tension due to heating from excessively high-amperage flow—often because of prolonged cranking or low battery voltage. It can be evidenced by blued or even charred brush springs.

- Damaged field coils: Insulation can break down, causing shorts between coils or shorts to ground. This can be caused by age, contaminants breaking down the insulation, or excessive current flow. Excessive heat may also cause connections to be melted, creating additional resistance in the circuit.
- Damaged armature: An armature may have the commutator excessively worn or unevenly worn. The armature may also develop shorts between the windings, shorts to ground, and opens between windings and the commutator. A test instrument called a growler is used to test an armature.
- Worn bushings or bearings: Sintered brass bushings or, in some cases, bearings are used to suspend the armature in the starter case. Because motor efficiency is dependent on having the smallest clearance between the armature and field coils, any wear of bushing or bearings will cause contact between the armature and field coils. Worn bushing or bearings cause excessive current draw that can be observed during a starter draw test.

Use **TABLE 14-1** to assist in diagnosing starting system problems. Always consult manufacturers' information before commencing any work.

These tests are explained in the following sections:

- Available Voltage Test
- Starter Current Draw Testing
- Testing Starter Circuit Voltage Drop
- Inspecting and Testing the Starter Control Circuit
- Inspecting and Testing Relays and Solenoids

Available Voltage Test

If the starting system complaint is slow cranking, the available voltage test is recommended. This test measures the amount of voltage at the starter battery positive cable and ground stud on the starter, if equipped. Minimum available voltage to the starter must not fall below 10.5 volts after three consecutive cranking periods of 30 seconds, with a 2-minute cooling period between each cranking period. If the voltage falls below 10.5 volts, the electrical system may not have adequate current to energize injectors or operate ECMs, even though cranking speed is adequate.

To measure available voltage, first disable the engine from starting by removing a fuse for the ECM, disabling the shut-off solenoid, or by an alternative method. Then, connect a voltmeter between the starter ground stud and battery positive terminal on the solenoid. While cranking the engine, measure and record the amperage and voltage and evaluate the results.

TABLE 14-1 Starting System Diagnosis Chart

Concern	Possible Cause	Remedy
Engine cranks slowly, does not start	Discharged battery	Charge; test and replace if necessary
	Very low temperature	Allow battery to warm up; check circuits and battery
	Battery cables too small or poor connections	Install correct battery cables or clean and replace connections
	Defective starter motor	Test; repair or replace as needed
	Engine malfunction	Check engine for low oil or mechanical problems
Solenoid clicks, chatters	Loose or corroded battery terminals	Remove, clean, reinstall
	Battery discharged	Charge; test and replace if necessary
	Wiring problem inside solenoid	Replace solenoid
Lights stay bright, vehicle does not crank	Open circuit in starter	Disassemble and repair or replace starter
	Open circuit or high resistance in circuit	Check solenoid, relays, and neutral start switch or clutch switch; repair or replace if needed
	Open circuit in safety switch	Check; repair or replace switch
Lights dim greatly, vehicle does not crank	Discharged or malfunctioning battery	Charge and test battery; replace if necessary
	High resistance at battery connection	Clean and tighten terminal connections
	Loose or corroded battery terminals	Remove, clean, reinstall
	Very low temperature	Allow battery to warm up; check circuits and battery
	Pinion not engaging ring gear	Check for damaged parts and alignment of starter
	Solenoid engaged but not cranking	Check starter motor and connections
	Pinion jammed—starter and flywheel out of alignment	Check pinion and gear teeth
	Stuck armature in starter	Replace or repair starter
	Short in starter	Check engine for low oil or mechanical problem
	Engine malfunction	Charge and test battery; replace if necessary
Lights out, vehicle does not crank	Poor connection (probably at battery or earth)	Clean cable clamp and terminal; tighten clamp
	Open circuit	Clean and tighten connections; replace wiring if necessary
	Discharged or faulty battery	Charge and test battery; replace battery if necessary
Whine or siren sound just after starting	Overrunning clutch defective	Repair or replace as needed
	Solenoid plunger sticking	Repair or replace solenoid
	Weak return spring	Replace spring
	Damaged flywheel ring gear teeth	Remove and replace
	Pinion jammed, too tight—starter and flywheel out of alignment	Check pinion alignment with gear teeth; shim if necessary
Starter turns, engine does not	Pinion not engaging—starter and flywheel out of alignment	Check pinion alignment with gear teeth; shim if necessary
	Pinion slipping	Replace or repair starter
	Damaged flywheel ring gear teeth	Remove and replace
Pinion disengages slowly when engine starts	Solenoid plunger sticking	Repair or replace solenoid
	Overrunning clutch defective	Repair or replace as needed
	Weak return spring	Replace spring
	Pinion jammed, too tight—starter and flywheel out of alignment	Check pinion alignment with gear teeth; shim if necessary

► Starter Current Draw Testing

SI4001

Testing starter motor current draw is the best indicator of overall cranking system performance. Manufacturers specify the current draw for starter motors, and any tests must be performed with a fully charged and correct capacity battery for the machine. Starter motors can be tested in two ways: on machine or off machine. The on-machine test is usually called a starter draw test, and the off-machine test is called a no-load test. Manufacturers provide specifications for one or both of the tests.

If the starting system complaint is slow cranking, a starter draw and available voltage test is recommended, using the following steps:

1. The engine is disabled from starting by removing a fuse for the ECM, disabling the shut-off solenoid, or by an alternative method.
2. A voltmeter is connected between the starter ground stud and battery positive terminal on the solenoid.
3. An inductive type amp clamp is placed over the either battery cable to the starter.
4. While cranking, the amperage and voltage are measured and recorded.

Results are compared with the manufacturer's specifications found in a shop manual. Properly charged batteries with adequate capacity should not allow available voltage to fall below 10.5 volts during cranking (**FIGURE 14-31**).

If cranking speed is low, and amperage measured is below normal but available voltage is high, the starting motor or starting circuit has high resistance. Worn brushes or loose or burnt internal connections could cause this condition.

If amperage drawn by the starting motor is high and available voltage low, the starter may be defective internally, the engine seizing or resistive, or the battery voltage low. Shorted field coils caused by the armature contacting the coils are a likely cause of an internal defect. Low available voltage to the starter may also be the cause. Undersized cables, loose connections, or a corroded and highly resistive connection reduce available voltage to the starter, causing excessive amperage draw. Each electrical connection and cable in the starter circuit has to be measured for voltage loss due to excessive resistance in this situation. Small resistances will become larger as amperage increases, predicted by Joule's heating law. Resistive wire or connections will drop voltage and heat up at the same time. By using a carbon pile to load cables and circuits to 500 amps, voltage loss should not total more than 5% in a 12-volt circuit (0.5 volt), with no more than 2% loss in any single cable.

FIGURE 14-31 Positioning of the voltmeter to measure voltage drop across different parts of the starter circuit.

There is no “fixed” amount of amperage draw for each and every engine. However, no more than 1 amp per cubic inch of engine displacement should be observed. Manufacturers publish some guidelines for an engine or starter configuration. The amount of amperage used by a starter varies, however, due to the following reasons:

- Engine displacement—larger engines require more torque to turn and consequently more cranking amperage
- The compression ratio, which may change the amount of cranking torque
- The type of starter, direct drive or gear reduction, which changes the amount of amperage used.
- Mechanical condition of engine, which may be loose or tight due to varying mechanical conditions such as temperature, amount of lubrication, wear, bearing or piston seizure, ring condition, and combustion chamber deposits
- The starter drive-to-flywheel ratio
- The condition of the battery

To test the starter draw, follow the guidelines in **SKILL DRILL 14-1**.

► Testing Starter Circuit Voltage Drop

SI4002

The electrical circuit of the starter motor consists of a high-current circuit and a control circuit. The high-current circuit consists of the battery, main battery cables to the starter motor solenoid, solenoid contacts, and heavy ground cables back to the battery from the engine and chassis. The control circuit activates the starting motor solenoid and can be ECM controlled. Voltage drop can occur across both the high-current and control circuits.

A voltmeter is used to measure voltage drop across all parts of the circuit. A voltmeter with a minimum/maximum range

setting is very useful when measuring voltage drop because it will record and hold the maximum voltage drop that occurs for a particular operation cycle. Small resistance and poor connections are magnified when high amperage passes through the circuit—resistances that will not be observable when low amperage current passes through a circuit.

Voltage drop is tested while the circuit is under load. The voltmeter is connected in parallel across the component or part of the circuit that is to be tested for voltage drop. This means the voltmeter would be connected on either side of a terminal connection or either end of a cable. For example, to measure the voltage drop across a battery terminal, one voltmeter lead would touch the battery post, and the other end would touch the wire of the battery cable connected to the terminal, as close as possible to the post. When the starter is cranked, or a load applied through a carbon pile load tester, any resistance will be observed as a voltage reading. A high voltage reading indicates excessive resistance. Similarly, a voltmeter with long leads can be connected to each end of a battery cable. When the starter is cranked, cable resistance is observed with a voltmeter reading. In both cases, the voltmeter is simply measuring the voltage or pressure differential between two points.

To test starter circuit voltage drop, follow the guidelines in **SKILL DRILL 14-2**.

► TECHNICIAN TIP

A faulty battery affects voltage drop tests, so always ensure that the battery is fully charged and in good condition before performing tests.

► Inspecting and Testing the Starter Control Circuit

SI4003

The starter control circuit activates the starter solenoid, and the starter solenoid activates the starter motor. If there is a problem in the starter control circuit, the machine will likely not

SKILL DRILL 14-1 Testing Starter Draw

1. Research the specifications for the starter draw test. Place an inductive-type amp clamp over either the positive or negative cable. It doesn't matter which starter cable is measured, as it is a series circuit, so amperage will be the same at any point in the circuit.
2. Connect the AVR voltmeter leads to the battery or at the starter.
3. Make sure all of the appropriate wires are inside the clamp and that the clamp is completely closed.
4. Disable the engine from starting by removing a fuse from the engine ECM or disabling the injection system shut-off solenoid.
5. With the engine disabled, crank the engine, and record the amps and volts as soon as the amps stabilize.
6. Compare the readings with the specifications, and determine any necessary actions.

SKILL DRILL 14-2 Testing Starter Circuit Voltage Drop

1. Set the DVOM to "Volts." Connect the black lead to the positive battery post and the red lead to the positive battery terminal on the starting motor.
2. Crank the engine, and read the maximum voltage drop for the positive side of the circuit. Connect the black lead to the negative battery post and the red lead to the negative terminal or starting motor ground stud. Crank the engine and read the voltage drop.
3. If the voltage drop is more than 0.5 volt on either side of the circuit, use the voltmeter and wiring diagram to isolate the voltage drop. Conduct further voltage drop tests across individual components and cables. Determine any necessary actions.

crank over at all, or maybe intermittently. The control circuit is made up of the battery, ignition switch, neutral safety switch (automatic equipment), clutch switch (manual equipment), starter relay, and solenoid windings. If the starter is controlled by the ECM, then you must be aware of all of the circuits, such as the immobilizer circuit and the ECM itself.

To inspect and test the starter control circuit, follow the guidelines in **SKILL DRILL 14-3**.

► **TECHNICIAN TIP**

The starter relay bypass test is a quick method of determining whether the relay is operational. This test should be performed when the starter motor does not crank when the ignition is in the start position (or when the starter button is depressed). Connect a jumper wire between the battery and starter terminal on the relay. This connection bypasses the control circuit of the relay, so the engine should crank. If the engine cranks with the jumper installed, check to see whether current is

supplied to the relay when the ignition key or starter button is in the crank position. If current is available to the relay, check the ground supplying the control circuit to determine whether it is properly connected or resistive. If the control circuit is properly energized and the starter cranks when the jumper wire is used, the starter relay is defective. If the starter motor still does not crank, check the cables and other circuits to the starter:

► **Inspecting and Testing Relays and Solenoids**

S14004

The starting system typically contains solenoids and relays that activate the control circuit. The solenoid is mounted on the starter motor, and one or more of the starter circuit relays are found on the starter, or firewall.

SKILL DRILL 14-3 Inspecting and Testing the Starter Control Circuit

1. Use a DVOM to measure voltage between the solenoid control circuit terminal on the solenoid (R) terminal and the housing of the starter while the engine is cranking.
2. If the voltage is less than 10.5 volts, measure the voltage drop between the R terminal and the relay.
3. If the voltage drop is less than 0.5 volt, measure the voltage drop on the ground side of the relay control circuit.
4. If the voltage drop is higher than 0.5 volt on either side of the circuit, use the wiring diagram to guide you in isolating the voltage drop on that side of the circuit. Continue conducting voltage drop tests across individual components and cables.
5. If the voltage drops are within specifications on both sides of the circuit, the resistance of the solenoid pull-in and hold-in windings must be measured. If out of specifications, the solenoid or starter motor and solenoid will have to be replaced.

Before performing any tests, ensure that the machine battery is charged and in good condition. The manufacturer's wiring diagrams should be checked to determine the circuit operation, identification, and location of all components in the starter circuit.

Relays must be tested in two or three ways, depending on the relay. The simplest test is to measure the resistance of the relay winding. If it is out of specifications, the relay will have to be replaced. If it is okay, the contacts must be tested for an excessive voltage drop. The best way to do this is by using an adapter that fits between the relay and the relay socket. This will allow the normal circuit current flow to flow through the contacts so that a voltage drop measurement can be taken. Any excessive voltage drop across the relay contacts will require the replacement of the relay. The last test is used only on relays with a suppression diode in parallel with the relay winding. Connect a reasonably fresh 9-volt battery across the relay winding terminals in one direction, and then switch polarity by turning the battery around. If the diode is good, the relay should click in one direction and not in the other. If it clicks in both directions, the diode is shorted. If it does not click in either direction, either the relay winding or the diode is open.

Solenoids are tested by measuring the voltage drop between the battery terminal and motor terminal. The first test to perform is a voltage drop test across the solenoid contacts. Place the red lead on the solenoid B-positive input and the black lead on the solenoid B-positive output. The voltage drop should be less than 0.5 volts for a 12-volt system and less than 1.0 volt for a 24-volt system. If not, replace the starter assembly. Testing of the

solenoid winding requires partial disassembly of the solenoid. Therefore, it is usually best to disconnect the control circuit connector from the solenoid and use a jumper wire to activate the solenoid. If the solenoid and starter operate, there is probably a fault in the machine's control circuit that needs further testing. If the solenoid or starter does not work (and the circuit is grounded), then the starter is likely faulty and will have to be replaced.

To inspect and test relays and solenoids, follow the guidelines in **SKILL DRILL 14-4**.

► Removing and Replacing a Starter and Inspecting the Ring Gear or Flexplate

SI4005

The starter motor will have to be removed to check for on-bench testing, poor drive engagement, or starter motor overhaul or replacement. The starter motor may be mounted in difficult-to-access locations. In some cases, other machine parts may have to be removed before the starter itself can be removed. Access to both the topside and underside of the machine may be required to remove mounting bolts. It may also be necessary to have another technician assist you to remove the heavy starter motor from machine.

To remove and replace a starter motor and inspect the ring gear or flexplate, follow the guidelines in **SKILL DRILL 14-5**.

SKILL DRILL 14-4 Inspecting and Testing Relays and Solenoids

1. To test a relay, measure the resistance of the relay winding, and compare with specifications. If the relay is out of specifications, replace it.
2. Use a relay adapter to mount the relay on top of the relay socket so you can check the control circuit wiring and perform voltage drop tests on the contacts.
3. Activate the relay while measuring the voltage across the relay winding. If it is near battery voltage, the control circuit wiring is okay.

4. Measure the voltage across the contacts with the relay not activated. This should read near battery voltage if both sides of the switched circuit are okay. If not, perform voltage drop tests on each side of the switch circuit.
5. Activate the relay while measuring the voltage drop across the contacts. If it is more than 0.5 volt, the relay will have to be replaced.
6. To test a starter solenoid, measure the voltage drop across the solenoid contact terminals with the key in the crank position. If it is more than 0.5 volt, replace the solenoid or starter assembly.
7. If the solenoid does not click with the key in the crank position, remove the electrical connection for the control circuit at the solenoid.
8. Use a jumper wire to apply battery voltage to the control circuit terminal on the solenoid and see if the solenoid clicks. If it does, then there is likely a fault in the control circuit wiring. If the solenoid still does not click (and the circuit is grounded), then the solenoid windings or starter brushes are likely worn (sometimes tapping on the starter while the key is turned to the crank position will free up the brushes enough that the pull-in winding can operate). Determine any necessary actions.

SKILL DRILL 14-5 Removing and Replacing a Starter Motor and Inspecting the Ring Gear or Flexplate

1. Locate and follow the appropriate procedure in the service manual.
2. Disconnect the battery ground and electrical connections to the starter motor.
3. Loosen the mounting bolts, leaving them in place until you are ready to remove the starter motor.
4. Remove the starter motor by supporting its weight while the mounting bolts are removed. You may need assistance to support the weight of the starter while this step is being conducted.
5. Examine the starter drive for any wear to the drive teeth.
6. Using a work light, inspect the ring gear or flexplate teeth for damage. Slowly turn the engine over while checking the ring gear or flexplate, ensuring the circumference is inspected. In difficult-to-see locations, an engine borescope may provide assistance. Report and report any damage to the ring gear.
7. Reinstall the starter motor by reversing steps 1 through 4 above.

► Overhauling a Starter Motor

SI4006

Overhauling a starter motor requires the disassembly and checking of all component parts. The starter motor component parts should also be cleaned and replaced or repaired, and lubricated as necessary. Always mark the position of the housings in relation to each other before commencing disassembly. This ensures that the housings are correctly aligned when reassembled. Each starter motor is unique and may require slightly different disassembly and overhaul procedures. Always consult the manufacturer's procedures for the specific starter motor on which you are working.

Note that the assembly procedure is the reverse of disassembly. When assembling, be sure to correctly lubricate all lubrication points. Check the manufacturer's procedure for the lubrication points and type of lubricant.

Once the starter motor has been disassembled into its component parts, conduct the following tests for each component as follows:

- Solenoid:
 - Test the resistance and current draw of the pull-in and hold-in windings.
 - Check for the free movement of the iron core.
 - Check contacts and terminal end cap for wear and cracks. Make replacements if necessary.
- Drive and yoke:
 - Visually inspect the drive engagement yoke for wear and damage. Replace if there is excessive wear.
 - Check the drive clutch for slippage. If there is excessive slippage, replace the drive.
- Brushes:
 - Check the length of the brushes with the manufacturer's specifications and replace if necessary.
 - Check the brush springs for tension, brush movement in the brush holder, and the insulation of the brush holder.
- Field windings:
 - Visually check the insulation for cracks or damage. Check for short circuits through the field insulation and case by connecting a 110-volt test lamp between the field coil and case. If the lamp lights, there is a short circuit. If the field insulation fails, the field will have to be replaced or reinsulated.
- Armature:
 - Check the armature on a growler for shorts between windings. Using a thin metal strip, rotate the armature. A vibrating strip means the armature is shorted and requires replacement. However, before condemning it, check to ensure there are no shorts between the commutator segments. Retest if you find any.
 - Also check the armature insulation to ground using an insulation tester or the insulation tester fitted to the growler. Use an insulation test no higher than 110 volts for a 12- or 24-volt armature. Note that to pass an insulation test, the armature must be dry and free of contaminants.
 - If the armature fails either test, it must be replaced.
 - Machine the commutator in a lathe if it is worn.
 - Check the armature shaft for wear or damage to the bearing surfaces. Also check the drive splines for wear or damage. Check the laminations for damage. Check the shaft to ensure it is not bent. Check the windings to

SKILL DRILL 14-6 Overhauling a Starter Motor

1. Locate and follow the appropriate procedure in the service manual.
 2. Remove the bearing end cap and circlip from the brush end.
 3. Remove the solenoid and the yoke securing pin of the starter motor if it is fitted.
 4. Remove the through bolts holding the starter motor together.
 5. Prize the starter motor apart while checking for any remaining screws or bolts.
 6. Remove the brushes from the brush holder if necessary.
 7. Slide the armature out of the main casing.
 8. Remove the drive circlip, and remove the drive assembly.
 9. Clean, test, and inspect all component parts. Use specialized testers where necessary, for example, growler to test the armature, insulation tester to test fields and armature, and DVOM to check resistances of solenoid windings.
 10. Replace any faulty components. You may need to arrange for the commutator to be machined to make it true.
 11. Remove and replace the bushings into the end housing. Ensure bushes are pre-oiled if they are the sintered type.
- Bushings have to be driven or pressed out or using a bushings drift punch.
12. If the brushes require replacement, disconnect or desolder them, and replace them.
 13. Reassemble the drive to the armature, ensuring it is appropriately lubricated.
 14. Reassemble the armature into the main case, and locate the brushes. At this stage, the drive yoke and securing pin may have to be fitted. In some cases, the securing pin is not fitted until after the armature is in place.
 15. Assemble the main case and end housing securing with the through bolts.
 16. Reassemble the solenoid, its connections, and the brush end armature circlip. Ensure the appropriate lubrication if fitted.
 17. Check to ensure that all components are fitted and the drive and armature are free to move.
 18. Test the starter motor in the test bench.
 19. Clean the work area, and return tools and materials to proper storage.

ensure they are not damaged or bent. Any damage to the above items means the armature should be replaced.

- Housings:
 - Check the housings for damage or wear. Replace if they are cracked or broken.
- Bushes:
 - Check the bushings for wear, using the armature bearing surfaces. Replace the bushings if they are worn.
 - When replacing bushings, use soft bush drifts to drive or press the bushes into and out of the housing.
 - Oil sintered bushings before fitting them into housing.
 - Some bushings may require machining to size once they are fitted into the housing.

Once the starter motor has been overhauled, it should be tested on a starter test bench with a full load if possible. If a full load test is not possible, conduct a no-load bench test as per the

procedure in this chapter. To overhaul a starter motor, follow the guidelines in **SKILL DRILL 14-6**.

Engine and Starter Rotation

When observing engine rotation, many technicians often note the front engine pulley/harmonic balancer turns clockwise. However, not all engines are mounted in-line with the driveline (e.g., “V” drives). Some engines are mounted sideways in a machine, and some are mounted at the rear and sideways. Because there is an abundance of configurations including engines in machine applications, the SAE references engine rotation from the flywheel end of the engine. Most automotive style engines are left hand, or counterclockwise, rotation.

The location and position of the starter on the engine can determine which direction the engine is cranked. Starter drive mechanism and the cut of the teeth will be changed along with helix features of the armature that may move the drive.

Wrap-Up

Ready for Review

- ▶ The starting system provides a method of rotating (cranking) the machine's engine to begin the combustion cycle.
- ▶ Diesel engines require large starter current draw, so several batteries are often connected in parallel of series to increase available cranking amperage or voltage.
- ▶ New designs of starter motors and systems controls are enabling starters to last longer and increase output torque while substantially reducing motor weight.
- ▶ There are three major categories of electric starters used in off-road mobile equipment: direct drive, reduction, and planetary gear reduction.
- ▶ The three most common types of DC motors found in off-road mobile equipment are series, shunt, and compound motors.
- ▶ Series motors are called “series” because the current pathway through various components inside the motor is in series. Because it is a series circuit, any unwanted resistance inside the motor, whether it is a burnt contact

or loose brush, will reduce current flow throughout the entire motor circuit.

- ▶ Series wound motors also are self-limiting in speed due to the development of a counter-electromotive force (CEMF) that induces current in the opposite direction of battery current through the motor.
- ▶ Cranking an engine with low battery voltage is destructive to a starter motor.
- ▶ Regardless of the motor design, a starter motor consists of housing, fields, an armature, a commutator, brushes, end frames, and a solenoid-operated shift mechanism.
- ▶ Some starter motors are equipped with over-crank protection thermostats that will open the relay circuit and interrupt the current to the solenoid if prolonged cranking causes the motor temperature to exceed a safe threshold.
- ▶ Another protection device for the starter control circuit is the automatic disengagement lockout, which prevents the starter motor from operating if the engine is running.
- ▶ Dual-voltage systems allow the off-road mobile equipment to be started on 24 volts for improved electrical efficiency, and the other electrical loads operate on the more common 12 volts.
- ▶ The starting system is just part of the overall machine's electrical and mechanical system. As such, there are areas of overlap between the various electrical and mechanical systems on the machine.
- ▶ Whether a slow-crank or a no-crank condition, failure to crank over properly can be caused by electrical or mechanical problems. It is important to be able to differentiate between the two types of faults so that a wrong diagnosis can be avoided and the problem fixed appropriately the first time.

Key Terms

armature The only rotating component of the starter; has three main components: the shaft, windings, and the commutator.

automatic disengagement lockout (ADLO) A device that prevents the starter motor from operating if the engine is running.

counter-electromotive force (CEMF) An electromagnetic force produced by the spinning magnetic field of the armature, which induces current in the opposite direction of battery current through the motor.

direct drive A starter motor drive system in which the motor armature directly engages the flywheel through a pinion gear.

frequency-sensing relay A relay connected to the alternator that detects alternating current only when the alternator is charging.

low-voltage burnout A damaging condition for starter motors in which excess current flows through the starter, causing the motor to burn out prematurely.

over-crank protection (OCP) thermostat A thermostat that monitors the temperature of the motor and opens a relay circuit to interrupt the current to the solenoid if prolonged cranking causes the motor temperature to exceed a safe threshold.

planetary gear reduction drive A type of gear reduction system in which a planetary gear set reduces the starter profile to multiply motor torque to the pinion gear.

reduction gear drive A starter motor drive system in which the motor multiplies torque to the starter pinion gear by using an extra gear between the armature and the starter drive mechanism.

Review Questions

1. Which of the following statements about the starting/cranking system is correct?
 - a. On ECM starting systems, the ECM controls the operation of a relay to energize the starter circuit.
 - b. Data supplied by other on-board network modules, along with control algorithms in the module, determine when and for how long the starter will crank.
 - c. A control circuit determines when and if the cranking circuit will function.
 - d. All of the choices are correct.
2. In diesel engines, what is the most common ratio between the flywheel ring gear and pinion gear?
 - a. 10:1
 - b. 15:1
 - c. 17:1
 - d. 20:1
3. What is the minimum life expectancy for a modern starter?
 - a. 2 years with 4,000 start cycles
 - b. 3 years with 5,000 start cycles
 - c. 4 years with 7,000 start cycles
 - d. 5 years with 9,000 start cycles
4. Which of the following common electric motors develop the highest torque and are used as starter motors?
 - a. Stepper
 - b. Compound
 - c. Shunt (parallel wound)
 - d. Series
5. Which of the following statements concerning current flow for a series motor is correct?
 - a. Current passes through the armature via the commutator and leaves through the second brush connected to the field winding.
 - b. A magnetic field is created in the armature.
 - c. Current passes through the windings of the field coils.
 - d. All of the choices are correct.
6. Which of the following is *not* a component of a starter?
 - a. Field coils
 - b. Rotor
 - c. End frames
 - d. A solenoid-operated shift mechanism
7. Which of the following is *not* a main component of the armature?
 - a. Shaft
 - b. Body
 - c. Windings
 - d. Commutator

8. Which of the following statements about the commutator is correct?
 - a. The commutator assembly presses onto the armature shaft.
 - b. The commutator is made up of heavy copper segments separated from each other and the armature shaft by insulation.
 - c. The commutator segments connect to the ends of the armature windings.
 - d. All of the choices are correct.
9. Which of the following statements about starter control circuits is correct?
 - a. In its most basic form, the starter control circuit has an ignition switch directly controlling the starter solenoid to operate the starter motor.
 - b. In modern machines, the circuits are more complex, because relays and control circuits, such as transmission neutral and clutch switches, are added to improve reliability and the safety of machines.
 - c. The latest models of machines use an electrical system control module, which interfaces with the on-board network that receives data from various sensors, and various sensors to control the operation of the starter control circuit.
 - d. All of the choices are correct.
10. A possible cause of a solenoid clicking and chattering is _____.
 - a. loose or corroded battery terminals
 - b. short in the starter
 - c. an open circuit
 - d. a slipping pinion

ASE Technician A/Technician B Style Questions

1. Technician A says that dozens of electric motors are found in off-road equipment operating a variety of devices from electric seats, fuel and coolant pumps, fan blower motors, and even instrument gauges. Technician B says that the largest of all these electric motors is the starter motor. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
2. Technician A says that all electric motors operate using principles of magnetic attraction and repulsion. Technician B says that because like magnetic poles attract one another and unlike poles repel, it is possible to arrange magnetic poles within the motor to be continuously in a state of repulsion and attraction. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
3. Technician A says that the series and shunt motor are the two most common types of motor found in the mobile off-road equipment industry. Technician B says that series motors are called “series” because the field and armature windings are connected in series. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
4. Technician A says that series-wound motors also are self-limiting in speed because of the development of a counter-electromotive force (CEMF). Technician B says that CEMF is produced by the spinning magnetic field of the armature, which induces current in the same direction of battery current through the motor. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
5. Technician A says that cranking an engine with low battery voltage causes one of the most damaging conditions for a starter. Technician B says that low-voltage burnout occurs when excess amperage flows through the starter, causing the motor to burn out prematurely. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
6. Technician A says that the starter housing, or frame, encloses and supports the internal starter components, protecting them and intensifying the magnetic fields produced in the field coils. Technician B says that in the starter housing, field coils and their pole shoes are securely attached to the inside of the iron housing. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
7. Technician A says that different from the thin wire used in shunt motors, armature windings are made of heavy, flat, copper strips that can handle the heavy current flow of the series motor. Technician B says that in a four-brush motor, the halves of a coil are wound at 60 degrees to each other. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
8. Technician A says that the solenoid on the starter motor switches the high current flow required by the starter motor on and off. Technician B says that the solenoid on the starter motor engages the starter drive with the pinion gear. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B

9. Technician A says that the starter drive transmits the rotational force from the starter armature to the engine via the ring gear that is mounted on the engine flywheel or torque converter. Technician B says that in the past, gear reduction starters were used but that today, direct-drive starters have replaced them. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
10. Technician A says that some starter motors are equipped with an over-crank protection (OCP) thermostat. Technician B says that the thermostat monitors the temperature of the motor. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B

CHAPTER 15

Charging Systems

Knowledge Objectives

After reading this chapter, you will be able to:

- **K15001** Identify and explain the function and operating principles of the alternator.
- **K15002** Identify and explain the construction and operation of the charging system.
- **K15003** Identify and explain recommended procedures for diagnosing charging system complaints.

Skills Objectives

After reading this chapter, you will be able to:

- **S15001** Replace a serpentine belt.
- **S15002** Perform a charging system output test.
- **S15003** Measure alternator output cable circuit voltage drop.
- **S15004** Inspect, repair, or replace connectors and wires of charging circuits.
- **S15005** Remove, inspect, and replace an alternator.
- **S15006** Overhaul an alternator.

► Introduction

Compared with older off-road equipment, modern off-road equipment is increasingly dependent on electronic and electrical systems that require a constant and reliable supply of electrical power. As modern off-road equipment becomes more sophisticated, adding more comfort and convenience items, alternators are working harder than ever to keep up with the demands of the electrical system. For example, years ago a DC generator supplying 8–45 amps of current was all that was needed to operate lights, wipers, and the horn and to charge the batteries. Today, the average 12-volt electrical system loads for a late-model off-road machine may add up to as much as 150 amps at peak (**FIGURE 15-1**). Lighting, electronic powertrain and hydraulic controls, power accessories, communication, telematic systems, and many smaller electrical accessories add to the load carried by alternators on the newest machines.

Both alternators and DC generators produce electricity by relative movement of conductors in a magnetic field. That movement induces an electrical potential or voltage within the conductors. The key difference between an alternator and a DC generator is which component rotates or moves to generate electricity. In the DC generator, the conductors that generate

power rotate as part of the armature, and the armature rotates within a magnetic field created by the stationary pole shoes. In the alternator, the magnetic field is created by the rotor, which rotates within the stationary stator windings to generate electricity there. In both cases, there is relative movement between the magnetic field and the conductors.

► Alternator Functions

K15001

The charging system provides electrical energy for all the electrical components on the machine. The main parts of the charging system, as illustrated in **FIGURE 15-2**, include the battery, the alternator, the voltage regulator (which may be integrated into the alternator), a charge warning light or voltmeter, and wiring that completes the circuits.

The battery stores an electrical charge in chemical form, acts as an electrical dampening device for variations in voltage or voltage spikes, and provides the electrical energy for cranking the engine. Once the engine is running, the alternator—which is connected to the engine and driven by a drive belt—converts some of the mechanical energy of the engine into electrical energy to supply energy to all the electrical components of the machine. The alternator also charges the battery to replace the energy used to start the engine. The voltage regulator circuit maintains the optimal battery state of charge by sensing and maintaining a required charging system output voltage.

Older machines have separate (discrete) regulators mounted on the firewall or frame. Later, charging systems included regulators that were incorporated inside the alternator. Electrical system control modules, or ECMs, are now used to regulate the charging system more efficiently by controlling alternator output based on a number of parameters, such as electrical loads, engine load and rpm, alternator capability, battery type and temperature, fuel economy benefits, and more.

Battery technology is also altering the charging requirements of alternators. For example, more OEMs are using absorbed glass mat (AGM) batteries now because AGM batteries are capable of absorbing an electrical charge of up to

FIGURE 15-1 A typical off-road equipment alternator.

You Are the Mobile Heavy Equipment Technician

There is an excavator that has had numerous service calls for jump-starting because the batteries often go dead. Service calls are taking place almost every day, causing a high level of aggravation to the customer and the service center where you work. On previous occasions, the batteries have been replaced. In addition, the charging system output has been measured and found to be OK. Furthermore, the presence of parasitic draws has been checked, and none were found. The excavator operator has often been blamed for the problems, assuming that they have left lights or other accessories on, draining the battery. Out of frustration, the service manager has asked you to accompany the excavator operator for a day to find out when the excavator batteries drain and whether electrical loads are left on. After the excavator has stopped for a 45-minute break, you find the batteries are dead. Checking the alternator, you discover that the back of the alternator where the rectifier bridge is located has become excessively hot to touch. Finally, the cause has been found. Before explaining the fault to the customer, you'll need to answer the following questions:

1. Why has the rectifier bridge of the alternator become hot to touch while the engine was shut down?
2. During previous checks of the charging system, what inspection procedure would have identified that fault?
3. What component has failed in the rectifier bridge? Be specific.

FIGURE 15-2 A typical 24 VDC charging system diagram.

five times faster than older flooded-type lead acid batteries. Different battery types and variations to cell chemistry also result in differences to required charging voltages, the charging voltage profile or the charge rate over time, and the state of charge voltage readings. Modern charging systems need to adapt to these various challenges, and in many cases, this is achieved through the use of electrical system control module (ECM) control over the charging system.

Alternator Advantages

Alternators have not always been used on mobile off-road equipment. Until the 1960s, DC generators were used to supply direct current to the electrical system and charge batteries. The current produced by DC generators became inadequate as machine electrical loads increased. Generators were especially inefficient at low speeds, leading to a discharged battery condition after long idle periods. The development of low-cost solid-state rectifiers in the 1950s made the use of alternating current “generators” (alternators) possible. Alternators are much more efficient at producing current than DC generators. Alternating current—not direct current—is produced inside an alternator. Several pairs of diodes, referred to as the rectifier bridge, have the job of converting AC current to usable DC current.

Thanks to solid-state electronics and circuitry, alternators have become the dominant design due to their superior operating characteristics compared to generators:

- Alternators weigh less per ampere of output.
- Alternators have fewer moving parts.
- Alternators can produce power at engine idle speeds; generators cannot.
- Alternators can be operated at much higher speeds.
- Alternators use a lighter rotor, compared to a heavy armature in generators.
- Alternators conduct less current through the brushes if equipped, thus reducing wear.

- Alternators do not require current regulators; they control their own maximum amperage output.
- Alternators will produce current when rotated in either direction. Polarity from generators will change when rotated in the opposite direction. Note that cooling fans in alternators can turn only in one direction.
- Alternators allow the reduction of battery capacity due to faster recharging rate.

Alternator Principles

The alternator converts mechanical energy into electrical energy by electromagnetic induction (**FIGURE 15-3**).

In a simplified version, a bar magnet rotates in an iron yoke, which concentrates the magnetic field. A coil of wire is wound around each end of the yoke. As the magnet turns, voltage is induced in the coil, producing a current flow. When the north pole is up and the south pole is down, voltage is induced in the coil, producing current flow in one direction. As the magnet rotates and the positions of the poles reverse, the polarity of the voltage reverses as well. As a result, the direction of current flow also reverses. Current that changes direction in this way is called alternating current (AC). In this example, the change in direction occurs once for every complete revolution of the magnet.

Alternating Current

The two most important parts in an alternator used to produce electrical current are the rotor and stator winding. The rotor contains a spinning electromagnet that induces current flow in the stator winding, which is made up of numerous coils of wire. By varying the current supplied to the rotor’s electromagnetic coil, the strength of its magnetic field changes. The parts of the alternator are illustrated in **FIGURE 15-4** and will be discussed in detail in the section Alternator Components.

FIGURE 15-3 Electromagnetic induction.

FIGURE 15-4 An alternator. **A.** Rotor. **B.** Rotor winding. **C.** Battery-cable connection. **D.** Rectifier bridge. **E.** Stator windings. (2) **F.** Rotor shaft. **G.** Ventilated aluminum housing.

The amount of current produced from an alternator is proportional to the following four factors. The first is the strength of the magnetic field in the rotor. Increasing the strength of the magnetic field increases the force pushing and pulling on electrons in a stator winding. Stronger magnetic fields in the rotor translate directly to higher output voltage and amperage. The second factor is the speed at which the magnetic field rotates. The third factor is the angle between the magnetic field and conductors in the stator. The last factor is the number and/or size of conductors cutting magnetic lines of force.

Maximum amperage output of an alternator is limited by the speed at which an alternator rotates. As the alternator spins faster, a counter electrical current is induced in the stator by the continuously changing polarity of AC current in the stator windings. This induced current, called the counter-electromotive force (CEMF), opposes any increase in current induced in the stator by the spinning rotor. At high alternator speeds, the CEMF, which is induced in the opposite direction of output current by changing AC current polarity, will begin to equal any increase to the induced stator current. The result is CEMF. CEMF acts to reduce the output current of the alternator. The faster the alternator turns, the higher the CEMF produced in the stator (FIGURE 15-5).

FIGURE 15-5 Chart showing alternator output and current-limiting CEMF.

Alternator Classification

Alternators can be categorized by a number of variables, including whether voltage regulation is internal or external; the diameter of the housing; whether the alternator is sealed, oil cooled, or externally air cooled; amperage output; charging voltage; manufacturer; and many other factors. The SAE (the American Society of Automotive Engineers) classifies alternator automotive mounting configurations into standards to enable the adaptation of alternators from all manufacturers to fit engines. Two common mounting types for alternators are a pad-mount alternator (**FIGURE 15-6A**) and a hinge-mount type (**FIGURE 15-6B**).

► Alternator Construction

K15002

Regardless of the alternator's classification, all alternators share common components. Major components of the alternator are illustrated in Figure 15-4:

- Rotor—a rotating electromagnet that provides the magnetic field to induce voltage and current in the stator.

FIGURE 15-6 A. Pad-mount alternator. B. Hinge-mount alternator.

- Brushes/slip rings—make an electrical connection to the rotor field coil to supply current from the voltage regulator.
- Stator—stationary coils of wire in which current and voltage is induced by the magnetic field of the rotor.
- Rectifier—converts the AC induced voltage and current into a DC output.
- Voltage regulator—controls the maximum output voltage of the alternator by varying the amount of current flow in the rotor and therefore the magnetic-field strength.
- Cooling mechanism (air and oil)—in the case of air cooling, additional airflow is provided through the use of a cooling fan.
- End frames and bearings—alternators have two end frames, which fit together to house the components into a single unit. One end frame contains the rotor, the drive end bearing, and drive mechanism (usually a pulley). The other end houses the stator rectifier regulator and brush assembly.
- Drive mechanism—in most cases, a pulley drive is used, but direct-gear drive mechanisms may also be employed.

Rotor

The rotor provides the rotating magnetic field that cuts the wire coils within the stator to induce the flow of electrical current in the stator. The rotor consists of an iron core that encloses a coil of many turns of wire. Each end of the wire coil is connected to one of two conductive slip rings on the rotor shaft. The wire coil and slip rings are electrically insulated from the rotor shaft. Energizing the rotor's wire coil with typically 2 to 5 amps produces an electromagnetic field beneath two halves of the soft iron core. These two halves are arranged into claws or pole pieces.

The pole pieces have two purposes. One is to intensify the electromagnetic field, and the other is to arrange magnetic lines of flux produced in the coil into poles on each claw of the rotor. Each of the claws or pole pieces will have a stationary pole that alternates in sequence with each pole piece as north and south. A heavy alternator has more pole pieces or “claws”—typically between 12 and 16. For heavy-duty alternators, 14 is a common number of claws. Passing current through the rotor coil magnetizes the rotor claws. Alternating poles of magnetism are formed north–south–north–south on the rotor.

The output of the alternator is determined by a couple of the alternator's physical features. The first is the size and number of windings in the stator that is cut by the magnetic lines of force. The second is the strength of the magnetic field of the rotor. Increasing or decreasing the current flow through the rotor winding will change the magnetic-field strength. Usually the maximum possible amperage is 5 amps or less. Controlling the strength of the magnetic field is the job of the voltage regulator. **FIGURE 15-7** illustrates how the current flows through the rotor.

Brushes and Brushless Alternators

Regulated current to the alternator rotor is supplied through a pair of graphite brushes sliding against slip rings on the rotor shaft. The slip rings and the coil are electrically insulated from

FIGURE 15-7 Current flow through the rotor.

the rotor shaft. Lightweight springs help the brushes maintain contact with the slip rings. Brushes are designed to provide many hours of service life, but they eventually wear out. Dirt, fluids, engine blowby, corrosion, and other substances can leave residues on the slip rings or gum up the brush holders, also preventing good contact.

The service life of heavy-duty alternators should ideally last as long as a machine's, accumulating hours of service of up to 20,000 hours. One way to extend the service life is by using brushless alternator designs, such as the one illustrated in **FIGURE 15-8**, to bypass the problems of using brushes.

Instead of locating the magnetic field coil inside a rotating rotor, these alternators use a stationary field winding bolted to the alternator end frame. The rotor's pole pieces rotate around the stationary coil. Brushes, therefore, are not required to deliver the current to the rotor. As a result, there is no need to service the brushes and slip rings.

Exciting the Alternator

While the voltage regulator will supply current to the rotor, some alternators require some residual magnetism on the rotor before current is generated. **Residual magnetism** refers to the small amount of magnetism left on the rotor after it is initially magnetized by the coil's magnetic field. Residually magnetized rotors will begin to induce current in the stator windings when the alternator starts rotating without any current passing through the rotor coil. The stator, in turn, supplies current to the voltage regulator through exciter diodes. Normal alternator operation using a regulator will resume once current is supplied to the regulator. This category of self-exciting alternators generally features a single heavy-gauge battery cable connecting the alternator to the machine batteries.

Self-exciting alternators do not require the use of a circuit but may require some initial current in the rotor's coil through

the "R" terminal for the first time after installation or when the engine has been sitting without running for long periods. Often, equipment fitted with self-exciting alternators may require the engine rpm to be briefly increased after every start-up to initiate

FIGURE 15-8 A brushless alternator has rotating pole pieces around a stationary field winding. **A.** Rotor. **B.** Pole pieces (2). **C.** Stator windings. **D.** Stationary field coil.

charging. Using self-exciting alternators eliminates the need for a separate circuit from the key switch to the alternator and simplifies chassis wiring.

► TECHNICIAN TIP

Self-exciting alternators do not use a circuit connected to the ignition switch to switch on the voltage regulator and supply current to the rotor. Instead, they rely on residual magnetism found in the rotor after operating. If the alternator stays unexcited due to a prolonged shutdown period or after rebuilding, residual magnetism needs to be re-established. The “R” terminal is briefly energized with battery current using a jumper wire connected to the battery cable after the alternator starts. Once energized, the alternator will begin charging and should not need initializing with current again. Many alternators are regularly returned as defective because technicians are unaware of the procedure to excite the rotor initially.

Stator

The stator is made of loops of coiled wire wrapped around a slotted metal alternator frame. The laminated iron stator frame channels magnetic lines of force through the conductors, where current is induced by the spinning rotor. Because the wires are looped, with alternating magnetic north-south poles passing beneath the loops, alternating current is produced from the stator (**FIGURE 15-9**).

The windings are insulated from each other and also from the iron core. They form a large number of conductor loops, which are each subjected to the rotating magnetic fields of the rotor. The stator is mounted between two end housings, and it holds the stator windings stationary so that the rotating magnetic field cuts through the stator windings, inducing an electric

FIGURE 15-9 The stator consists of a cylindrical, laminated iron core, which carries the three-phase windings in slots on the inside.

FIGURE 15-10 Comparison between **A**, a low- and **B**, a high-current output stator winding.

current in the windings. To smooth the pulsating current flow, there are three distinct layers of windings offset 120 degrees in each layer from one another. This arrangement produces a more even flow of current from the alternator. The number of loops in each winding corresponds to the number of rotor poles. So, if the rotor has 14 poles, there will be 14 loops of wire in each of the three windings. Ultimately, the amount of amperage that the alternator is capable of producing depends on the mass of wire in the stator. A larger stator having more loops, more turns of wire in each loop, and/or thicker wire will have higher maximum output amperage than one with fewer loops, less wire, and thinner wire. **FIGURE 15-10** provides a side-by-side comparison of low- and high-output stators.

Phase Winding Connections

Two methods of connection can be used for the stator or phase windings: the Wye and Delta configurations. Both types of windings produce three-phase AC current, but voltage and amperage outputs differ. Windings connected in a Wye-type configuration have four connection points. As the name suggests, **Wye windings** resemble the letter “Y” (**FIGURE 15-11A**).

Three ends of each of the windings are connected to a point called the neutral junction. The other three free ends are connected to a pair of diodes in the rectifier bridge. The advantage of Wye windings is that they produce higher voltage at comparably lower rotor speeds. This means the alternator can begin charging a battery at lower engine speeds.

Delta windings, shaped like the symbol “delta,” are more popular in alternators for diesel engines (**FIGURE 15-11B**). These windings have only three connection points. The three junction points between the windings are connected to a pair of diodes found in the rectifier bridge. Because stator windings are connected in parallel, the resistance of Delta windings is one third less than Wye windings. Although Delta windings do not produce as much voltage as Wye windings at the same low rotor speeds, they do, however, produce substantially more amperage. Delta-wound alternators are best adapted to supply higher amperage output to charge multiple batteries and the heavy electrical loads found in trucks, buses, and off-road machines. More importantly, the steady high-speed operation of diesel engines combined with the higher efficiency of delta-wound

FIGURE 15-11 A. Wye-wound and B. Delta-wound stator configurations.

alternators at high speeds makes them better suited to use on diesel engines. Combination of Wye and Delta stators are rarely found in HD alternators.

Testing Stators

Stators, like rotors, are not normally serviced in a repair facility. However, when rebuilding, stators can be visually checked for burned, cut, or nicked winding laminations. Winding junction points are checked to ensure they are solid. Continuity should exist between all junction points of the stator. An amperage draw

test of each winding can be performed to check the resistance and balance of each section of winding. No continuity should exist between the windings and alternator frame. As illustrated in **FIGURE 15-12**, a stator can be tested for short circuits and open circuits.

A leakage-to-ground test evaluates winding insulation and is also known as an insulation stress test. Stress testing involves passing high-voltage, low-amperage current through the windings. Any breakdown in insulation is detected when continuity exists between the windings and frame.

FIGURE 15-12 A stator can be tested for short and open circuits.

FIGURE 15-13 Current flow through a single phase in the forward direction.

Rectifier

Alternators produce alternating current, which is acceptable for operating many electrical devices. However, not all AC-operated devices are cost-effective to produce or efficient to operate on mobile equipment. AC current cannot charge a battery either. Converting the AC current to usable DC current is referred to as **rectification**.

AC current is induced in the stator due to the movement of the rotors' magnetic fields. Alternating north-south poles passing over windings will alternately push and pull electrons. Moving the electrons in two different directions gives stator current flow its AC characteristic. The speed at which the lines of force cut the conductors, the angle the magnetic field cuts the stator conductors, the number of conductors, and the wire gauge will determine the amount of amperage induced in the stator.

Two diodes are connected to each wire end of either Delta- or Wye-wound stators. Each stator winding will produce one of three phases of AC current (**FIGURE 15-13**).

So, a minimum of six diodes is required to completely rectify all three phases of AC into DC. The silicon diodes making up the rectifier behave like a one-way electrical check valve. The two diodes connected to each winding will allow either a positive or negative current potential to appear at the output of the rectifier. If only a single diode is used at the end of the windings, only half the AC sine wave will be rectified. Two diodes enable full wave rectification (**FIGURE 15-14**).

The top of the waveform is called the **alternator ripple**. A ripple that is consistent across each winding indicates that the stator windings and diodes are each creating current flow and voltage consistently. An inconsistent ripple indicates a fault in either the diodes or the stator windings. Study the illustrations carefully so that you understand the role the diode bridge plays in providing the relatively smooth DC output required by the machine's systems.

FIGURE 15-14 Diode trio supplies power to the rotor circuit in most alternators. **A.** Ignition terminal. **B.** Voltage regulator. **C.** Diode trio. **D.** Stator connections (3). **E.** Rectifier bridge. **F.** Negative ground connection. **G.** Positive battery terminal. **H.** "R" terminal.

Rectifier Diode Problems

Heat can cause premature failures of diodes (**FIGURE 15-15**).

Additional cooling of rectifier bridges can be accomplished with heavier diodes and heat sinks or by connecting diodes in parallel so that six rather than three pairs accomplish the work. Another problem facing an alternator occurs when the diodes become open or shorted. An internally shorted positive diode will cause a parasitic loss of battery current through the alternator when the engine is not running. This condition will also cause a loss of up to 67% of alternator output because it interferes with the rectification of current from two winding phases. Shorted diodes can be detected with an AC voltmeter measurement of alternator output. Generally, any more than 0.4–0.7 volts of AC current superimposed over the DC output indicate that AC current is passing through a shorted diode. Most dedicated

FIGURE 15-15 Rectifier in an alternator housing. Note the fins on the heat sink to remove heat.

alternator testing equipment will have a diode ripple feature that detects this large AC waveform and illuminates a diagnostic light on the machine. Graphing the alternator output with a graphing

meter or oscilloscope and carefully observing the pattern also indicate the condition of the diodes. An open diode will not cause as much of a loss of output as a shorted diode—only up to 33% of output—but will cause increased fluctuations or pulsing of DC output current.

When measuring alternator output using an AC (not DC) voltmeter, AC current can normally be measured. An alternator with output voltage fluctuations between 13.9 to 14.2 volts DC, for example, will produce a 0.3-volt AC current. When graphed, the waveform looks like a ripple of a wave, hence the term AC ripple (**FIGURE 15-16**).

The voltage fluctuations are produced by the differences between the peak voltage of an AC sine wave and the minimum voltage found in the trough between sine waves (**FIGURE 15-17**).

AC ripple is suppressed by a capacitor inside the alternator and is absorbed by the battery. If AC ripple is too great, it leads to radio noise and electromagnetic interference (EMI) in many electronic control devices (**FIGURE 15-18**).

For example, an engine ECM may fail to function correctly, causing the engine to run rough. A powertrain module may even generate fault codes.

FIGURE 15-16 Typical alternator oscilloscope pattern showing AC ripple.

FIGURE 15-17 Three phases rectified.

FIGURE 15-18 Three phases not rectified.

Smoothing Capacitors

Capacitors can be used to smooth alternator AC ripple and prevent EMI. In the alternator, one is connected across the output to act like an electric shock absorber. When the output voltage increases slightly, the capacitor will charge and absorb the new increase. When voltage drops, the capacitor will drain current back into the circuit, topping up the output voltage, and then the capacitor is ready for a new charge.

TECHNICIAN TIP

A missing or defective alternator capacitor can cause radio noise and EMI interference with machine electronic modules. When checking for parasitic draws, the capacitor may give a false indication of current draw as it charges for a few seconds after the battery is disconnected. If batteries are disconnected for even a short time, they will spark when connected while the capacitor charges.

FIGURE 15-19 An external voltage regulator for a 24-volt alternator, with voltage regulator adjustment (circled).

Voltage Regulator

Voltage regulators are first classified as either external (FIGURE 15-19) or internal.

The majority of late-model alternators have internal regulators. Regulators can also be categorized by circuit connections used to supply current to the rotor used to induce “field excitation.” Knowing the type of field excitation circuit used is helpful when developing diagnostic strategies for testing alternators:

1. A-type regulators regulate the field current by controlling the resistance through to ground. One rotor brush is connected to the alternator output or battery positive (B+), and the other is connected to ground through the regulator (FIGURE 15-20).
2. B-type regulators control the battery positive supply to the rotor. One brush is connected directly to negative ground, and the regulator varies battery positive voltage supplied to the other brush. B-type circuits are used only by external regulators. If the electronic regulator fails or develops a resistive ground due to corrosion, it commonly causes the

FIGURE 15-20 A-type regulator connection.

alternator to overcharge, as system voltage is sensed through the ground and battery positive (FIGURE 15-21).

3. Isolated field-type of rotor excitation varies current through both the negative ground and battery positive (FIGURE 15-22).

In systems-integrated (SI) series Delco alternators, current supplied to the regulator is provided by the diode trio. These

FIGURE 15-21 B-type regulator connection.

FIGURE 15-22 An isolated field alternator allows connection of either an A- or B-type regulator.

three diodes will perform single-phase rectification of each phase of the alternators' windings. Single-phase rectification means only a maximum of half the alternators' voltage output can excite the rotor.

Some voltage regulators use an analog voltage signal to modulate or change the strength of the magnetic field. This means that the current to the rotor continuously varies. As the alternator reaches its set point, the field current gradually diminishes. Digital regulators will use a pulse-width-modulated signal to control the magnetic-field strength. These alternators will have a duty cycle frequency interval of between 10 and 7,000 times per second. Within that frequency interval, the voltage regulator changes the length of "on-time" current applied to the rotor. Current is cycled on and off hundreds of times each second, and the duration of on-time increases as higher output is required.

Output current from an alternator varies with the strength of the rotor's magnetic field. Increasing or decreasing current flow through the rotor will change output. Low current through the rotor produces low output and vice versa with high current flow producing higher alternator output current. Changing electrical demands, varying engine speeds, and changing the battery state of charge all require rapid, continuous adjustments to output voltage.

Current or amperage regulation is a function of voltage regulation. To understand this, consider that an alternator's output depends on two factors: One is the regulator set point,

and the other is the machine's electrical system's total circuit resistance. An electrical system with a battery in a low state of charge, and many other electrical loads switched on, has low resistance. Multiple current pathways exist, which lowers total circuit resistance. Low resistance permits high amounts of amperage to flow out of the alternator. (Remember Ohm's law: voltage = amperage $\times$ resistance.) Because the alternator is connected to all these circuits, the voltage regulator will supply the highest possible current flow to the rotor for maximum magnetic-field strength. As the batteries charge and some loads are turned off, less amperage is needed, because electrical system resistance increases. Because electrical system resistance increases, the system voltage will rise as amperage is reduced. When the system voltage reaches the alternator's set point, the voltage regulator will turn off the current to the rotor until the voltage falls again.

Stated another way, using power and Ohm's law (power = volts $\times$ amps), then if 1,200 watts of power are needed to supply the electrical system, the voltage amperage combination could be 85 amps at 14.0 volts or 100 amps at 12.0 volts.

Voltage regulators controlled by the ECM are commonplace. Using engine speed, air intake temperature and other variables, the ECM will adjust charging voltage to match battery temperature. To reduce drag when cranking, no field excitation takes place until after the engine starts. Once the engine is started, current output is slowly raised to minimize rough engine operation caused by heavy alternator loads. If battery voltage is too low, engine idle speed can be increased. Communication between the ECM and voltage regulator takes place over the controlled area network (CAN) (FIGURE 15-23).

Charging System Set Point

Alternators must be capable of controlling the output of the DC current. There must be enough current to adequately charge the batteries but not so much current that it causes damage to the machine's electrical system. Voltage regulation for 12-volt systems will establish a maximum charging voltage, known as the set point. Charging voltage set point averages between 13.5 volts and 14.6 volts. This is 1.5 to 2.0 volts above the 12.6-volt open-circuit voltage for a typical 12-volt battery. Also, 24-volt systems use 27 and 28.4 volts for a typical set point. It is always advisable to check manufacturer specifications for correct charging voltage ranges for the machine and operating conditions. Charging at voltages above 15 volts (12-volt system) and 31 volts (24-volt system) causes

- batteries to gas excessively
- batteries to overheat and lose electrolyte through electrolysis
- battery plates to shed grid material, buckle, and generally become damaged by heat as the temperature rises above 125°F (52°C)
- machine electrical systems, control modules, etc. to be damaged by high voltage
- premature and extensive bulb failure and LED light failure.

FIGURE 15-23 ECM controlled alternator: **A.** CANbus connection. **B.** CANbus connection to dash for charge lamp. **C.** Monitoring signal. **D.** Control signal.

Undercharging leads to battery plate sulfation and grid corrosion. This is a condition where sulfate deposited on the plates during discharge is left too long. If left long enough, sulfate turns to a hard-crystalline structure and cannot be driven off by charging. Multiple battery installations are especially vulnerable to the problems of uneven charge rates causing plate sulfation.

Factors affecting the precise set point include the following:

- *The type of batteries*—flooded batteries (standard lead acid) charge at lower voltages than no-maintenance or AGM batteries. AGM batteries are more easily damaged by overcharging.
- *States of battery charge*—discharged batteries have low resistance to current compared to charged batteries. AGM batteries can absorb 40% more current than flooded and low-maintenance batteries can.
- *Temperature*—battery resistance to charging increases as temperatures decrease. Temperature sensors in voltage regulators can adjust set points. To warm up the battery, Delco CS alternators charge at 16.5 volts for the first few minutes after start-up when the weather is cold.
- *Idle time*—low engine speed operation requires higher set points to keep batteries charged.

When operating in environments where a spark from an alternator's brush could trigger an explosion or cause a fire, the alternator is sealed and heat is radiated through the housing. Most alternators, however, rely on air to internally cool internal components (**FIGURE 15-24**).

If equipped with a cooling fan, the alternator must rotate in a direction that will push air through the unit. Today most cooling fans will push air through the alternator regardless of rotational direction.

FIGURE 15-24 A fan attached to rotor used to cool the alternator.

► TECHNICIAN TIP

The machine's electrical system can be severely damaged by high-voltage spikes if batteries are disconnected accidentally or intentionally while the alternator is charging. Since the rotor's magnetic fields do not disappear immediately and the battery is unable to absorb current, output voltage can suddenly rise to levels that can damage sensitive electronic devices. Some alternators include a **load-dumping** feature that temporarily suppresses these high-voltage spikes. This usually involves using specialized diodes in the rectifier bridges, which become resistive rather than conductive at a specific voltage level. The diodes are called **transient voltage suppression (TVS) diodes**. They will temporarily resist high voltage and automatically reset when the over-voltage goes away. Best practice is never to disconnect batteries when the engine is running.

Alternator End Frames and Bearings

The alternator housings support and enclose all of the alternator components and are typically constructed from aluminum (FIGURE 15-25).

Vents within the frames provide for a large amount of airflow to assist in dissipating heat. The housings accept the bearing assemblies, which support the rotor at the drive and slip ring ends. A pulley that is driven by a belt is mounted at the end of the rotor shaft. Most slip ring end frames also house the rectifier assembly. In some cases, the negative diodes are pressed into holes in the frame to provide a ground, while the positive diodes are mounted on insulated plates.

Drive Mechanism

A drive gear, rather than a pulley on rare occasions, is used to couple the alternator to the engine. It requires the alternator to be bolted directly to the engine in a location where a driving gear is available. This arrangement eliminates maintenance issues around belt tension and replacement but does require the alternator to be well sealed to prevent any oil leakage.

The correct gearing or pulley size needs to be selected for the alternator to ensure that the alternator does not over-speed at higher engine rpm but also produces enough output at idle to cater to electrical demand. Since an off-road diesel operates typically between 650 rpm and 2,100 rpm, a mechanical advantage between the alternator pulley and engine speed is needed to spin the alternator fast enough. Most larger alternators are limited to 8,000 rpm, which means the alternator drive ratio is precisely chosen to produce high output at idle yet stay below maximum speeds. This is particularly true because output curves tend to flatten out and brush and bearing wear increase with increasing speed. For large-bore diesel engines found in heavy off-road equipment, the driven ratio is approximately 2.7:1, which means that every engine rpm produces 2.7 rotor shaft revolutions. In recent years a ratio of 3:1 or even 3.1:1 is becoming common. At 2,000 rpm the alternator will turn 6,000 rpm. Some slow rpm diesels may

use a ratio as high as 5:1 in comparison to smaller-capacity, higher-revving engines that use a ratio as low as 2:1.

V-type belts and pulleys have been the traditional method of driving alternators. However, to extend belt maintenance intervals, manufacturers have moved completely away from using V-type pulleys in favor of serpentine belts equipped with automatic tensioners (FIGURE 15-26).

A serpentine belt is a type of multi-rib belt that is long enough to drive multiple accessories. Due to the length of the serpentine belt and the number of accessories it drives, idler pulleys are required to ensure each pulley has enough wrap or surface contact with the belt. Serpentine belt systems reduce belt wear while improving the coupling force with multiple accessories.

Belt tensioners can be spring-loaded or hydraulic, and they can absorb some of the torsional vibration found in diesels as the crankshaft accelerates and decelerates with each cylinder power and compression event (FIGURE 15-27).

FIGURE 15-26 A multi-rib serpentine belt.

FIGURE 15-25 Alternator end frames enclose and support all components and allow for maximum airflow through the alternator to remove excess heat.

FIGURE 15-27 A belt tensioner ensures the correct tension is applied to the belt to prevent slippage.

The alternator drive belt bears the brunt of this damaging force occurring as the engine acceleration rate changes and the alternator's mass resists the speed change. When the belt and alternator speed are out of phase, the belt is snapped and slips. This force is magnified by the 3:1 drive ratio between the crankshaft and alternator pulley. To improve belt life and mechanical efficiency, it is becoming common to use **overrunning alternator decoupler (OAD)** pulleys rather than a conventional solid pulley and tensioner. An OAD pulley uses an internal spring and clutch system that allows it to rotate freely in one direction and provide limited, spring-like movement in the other direction. The pulley acts like a shock absorber, absorbing the force associated with belt accelerations and speed reversals, enabling the alternator to freewheel when the belt suddenly decelerates.

Alternator Wiring Connections

The terms and connections used in this section are ones commonly used for machines. Different manufacturers may use different socket arrangements, color codes, and naming conventions for the various terminals and connectors on alternators, so it is always important to check manufacturer's wiring diagrams and naming conventions for information. The wiring requirements for alternators are relatively simple. This is particularly true for internal regulator self-exciting alternators because they use only a single battery cable (**FIGURE 15-28**).

The battery positive cable is large, red gauge wire—#4AWG (American wire gauge) or larger. It connects to the battery terminal on the starter and has voltage present at all times. Some alternators, particularly high-output ones, will also have a ground or negative cable. A large-gauge wire (#4AWG or larger) is connected to battery or chassis ground (**FIGURE 15-29**).

This prevents the engine block from conducting hundreds of amps that the alternator may produce and minimizes voltage loss. A remote sensing connection will also be used on some alternators and will usually be marked on the back of the alternator with an "S" (**FIGURE 15-30**).

FIGURE 15-28 Self-exciting alternators typically have only a main battery connection.

FIGURE 15-29 Circuit diagram for connection of self-exciting alternator.

The term **remote sensing** refers to the arrangement of directly connecting a terminal on the alternators voltage regulator to the battery in order to use battery voltage as reference point for regulating the alternator output voltage. This is different from simply using the large alternator to battery connection at the back of the alternator. Many alternators reference the battery positive connection at the alternator through this larger cable connection which often has lower voltage due to high amperage flow through the cable. Alternators that use **remote sensing** provide a more accurate direct reading of the battery at a regulator input terminal that is used for the regulator reference voltage. Remote sensing enables more accurate supply and adjustment of charging voltage to the batteries which help extend battery life. Without precise charging voltage supplied to the battery, its lifecycle is shortened through under and sometimes overcharging.

External regulator alternators will have additional connections to allow for field connections from the regulator to the alternator, as was shown in Figure 15-19. Provision for the connection of alternator warning lights may also be fitted to both internal and external regulator alternators.

Alternators that require external excitation will have an ignition excite or "I" connection. This small gauge wire has voltage present only when the ignition switch is in the run position. Current through this wire switches the voltage regulator on. In some machines built without voltmeters in the dash and equipped with an instrument cluster warning light, current will pass from the switch and to the light into the alternator regulator to provide initial excitation of the rotor's magnetic field. In most machines, however, voltmeters are used to indicate whether the charging system is properly functioning (**FIGURE 15-31**).

Another connection found on many alternators is the relay or "R" terminal. This terminal is connected directly to one phase of the stator winding. Because it is connected directly to the stator, it provides an AC signal whose frequency is related to the speed of the alternator. Because the speed of the alternator is related to engine speed, this signal can be used to operate a tachometer or an hour meter or to operate a frequency-sensitive starter lock out relay to disable the cranking circuit when the engine is running. Energizing or flashing this terminal, which is the temporary connection of battery voltage, is necessary on some self-exciting alternators in order to magnetize the rotor for

FIGURE 15-30 Remote sensing allows the voltage regulator to use battery voltage as a reference for alternator output voltage.

FIGURE 15-31 Instrument cluster warning light. When the alternator starts charging, charging voltage appears at the “I” terminal, which provides battery positive to both sides of the light and extinguishes the charging system warning light. In situations where a charge warning light is not required, an ignition feed may be directly connected to the “I” terminal.

initial start-up. Since the rotor is soft iron, the rotor will maintain this magnetism once it has been initially excited. However, after rebuilding or through prolonged inactivity, the rotor may lose the residual magnetism. For this reason, the relay terminal is needed on self-exciting single-wire alternators. This feature is

common to some Bosch and Delco SI series alternators, which use voltage regulators.

► Charging System Diagnosis

KI5003, SI5001

When diagnosing charging system problems, always start with the battery. A weak or dead battery, corroded battery-cable connections, and/or damaged or worn components may cause a no-crank or slow-crank problem. Check for dirt buildup on the battery top, case damage, loose or corroded connections, or any other trouble that could drain the battery charge. Charging system malfunctions are often identified by battery condition. Use **TABLE 15-1** to assist in diagnosing charging system problems.

Always consult manufacturers' information before commencing any work.

Inspecting, Adjusting, and Replacing Alternator Drive Belts, Pulleys, and Tensioners

If a problem arises with an alternator, perform a visual inspection of its drive belts, pulleys, and tensioners. An index mark on a belt tension indicates whether the belt is too loose or too tight. Ideally, the tensioner arm should be centered between the two stop points on the tensioner bracket.

TABLE 15-1 Charging System Diagnosis Chart

Concern	Cause	Remedy
Overcharged batteries	Resistive voltage sensing lead contact at alternator or electrical system	Repair
	Open voltage sensing circuit	Repair circuit
	Defective voltage regulator	Replace regulator
	Improperly adjusted voltage regulator	Adjust regulator
	One shorted battery in a battery bank	Replace battery
Low voltage or no-charge condition	Loose drive belts	Tighten or replace belt as necessary
	Corroded, broken, burnt, or loose wiring connections	Repair connections
	Undersize battery cables	Install proper gauge cables
	Defective batteries	Replace batteries as required
	Batteries too far from sensing lead contact	Reposition
	Missing sensing lead contact	Repair contact
	Defective voltage regulator	Replace regulator
	Improperly adjusted voltage regulator	Adjust regulator
	Defective rectifier bridge; shorted or open diodes	Replace or overhaul alternator
No magnetic field at alternator	Poor contact between brushes and slip rings	Overhaul alternator/replace brushes
	Damaged or worn brushes/slip rings	Overhaul alternator/replace brushes
	No residual magnetism present in the rotor	Overhaul/replace alternator
	Defective or improperly adjusted regulator	Adjust or replace regulator as required
	Open, shorted, or grounded rotor winding	Overhaul alternator/replace rotor
	No ignition excitation of regulator	Check and repair connection
	No current feed to internal regulator	Check and repair connection

Preventive Maintenance Practices

When performing preventive maintenance, the following areas require attention.

1. Cleaning cable terminals, wiring, and alternator connection points or corrosion. Alternator surfaces should be cleaned until they are free of accumulations of dirt, grease, and dust. Air passages need to be unobstructed to allow air to easily pass through. All connection points must be clean and free from corrosion since voltage is sensed from between ground and battery positive.
2. Mounting brackets should be inspected for loose bolts and to allow correct belt alignment. Broken and loose mounting may indicate damage from engine torsional vibration. If other accessory drive system components are functioning correctly, a sturdier model of alternator may be required.
3. Condition of belts and belt tension. A loose belt will slip and cause undercharging. Tensioners must be correctly aligned operating perpendicular to the belt. Multi-grooved belts should be checked for cracks, which may

FIGURE 15-32 Failure conditions for serpentine belts.

extend completely across the belt. The back side of the belt should not be worn and glazed.

Belts can have several issues, as shown in **FIGURE 15-32**.

To replace a serpentine belt, follow the guidelines in

SKILL DRILL 15-1.

SKILL DRILL 15-1 Replacing a Serpentine Belt

1. For safety reasons, disconnect the battery and lock out the machine. Inspect the belt for failure. Repair any condition causing belt contamination or failure due to misalignment.
2. Familiarize yourself with the belt routing. Draw a sketch, take a picture of the belt routing, or locate the belt routing diagram in a shop manual or on the radiator module.

3. Release the belt tension to remove the belt. To release belt tension, the automatic belt tensioner is retracted away from the belt using a wrench, socket wrench, 1/2" drive or 3/8" drive ratchet.
4. Inspect the drive belt pulley system for wear. Make sure the tensioner and the pulleys operate freely, without noise or looseness, and are in perfect condition. The tensioner pulley should contact the belt squarely; if not, the tensioner should be replaced. The installation of a belt kit containing a new tensioner and drive pulleys is recommended when replacing a belt at high accumulated mileage.
5. Before installing the new belt, inspect the alignment of the pulleys to prevent severe belt wear, damage, and belt noise.
6. Route and install the new belt according to the belt routing diagram. Align the belt ribs with the pulley grooves and ensure that the belt fits squarely on each pulley and all the belt grooves fit into the pulley grooves.
7. Release the belt tensioner once again to install the belt over the tensioner pulley. The automatic tensioner will apply the correct tension to the belt. When the installation tension is correct, unlock the machine, start the engine and observe if the belt drive and tensioning system is properly functioning.

► Charging System Output Test

SI5002

Machine charging systems are voltage regulated, which means that the alternator will try to maintain a set voltage across the electrical systems. As electrical load current increases in the machine systems, voltage starts to drop. The voltage regulator senses this voltage drop and increases the current output of the alternator, which in turn increases system voltage to try to maintain the correct voltage in the system. The testing of an alternator output initially involves the testing of the system's regulated voltage using a voltmeter. Regulated voltage is the voltage at which the regulator is allowing the alternator to create only a small charge due to the battery being relatively charged, as evidenced by the greatly reduced current output.

Unless the batteries are deeply discharged, the equipment headlights should not dim at idle when the alternator is operating satisfactorily. To performance test the charging system, also called a set point test, alternator voltage and amperage is measured with the engine running at 1,000–1,500 rpm. With all the machine loads switched off and the batteries fully charged, alternator output should be 20 amps or less and voltage should be 13.8–14.4 volts for a 12-volt system. Also, 24-volt systems should charge between 27.8 and 28.4 volts. If the voltage is not within this range and the regulator not adjustable, the alternator is likely defective.

An alternator's performance is tested under load and measured while the engine is at 1,500 rpm. A carbon pile tester is connected to the batteries, and the system is loaded until it

drops to 12.5 volts. At 12.5 volts, the amperage output from the alternator is also measured. Output should generally be within 10% of the alternator's maximum rating. This means that a 200-amp alternator should deliver at least 180 amps.

To differentiate between a defective regulator and the current generating section of an alternator, a full field test of the alternator is performed. This means that the voltage regulator is bypassed, and full battery voltage is supplied briefly to the rotor slip rings. The type of alternator circuit must be identified before performing this test.

"A" circuit alternators will ground one brush. In Delco alternators, ground is done by passing a screwdriver through the "D" tab at the back of the alternator. With the screwdriver against the alternator frame and the other end on a tab of the voltage regulator, a working alternator will begin to generate current. A voltmeter is used to measure output. If voltage rises, the regulator is defective and may be replaced instead of replacing the entire alternator.

"B" circuits will use a jumper wire connected to battery positive to full field. Isolated circuits will use two jumper wires. CAN-controlled alternators will provide diagnostic information needed to diagnose alternator problems. If current output does not rise after **full fielding**, it may indicate one of the following conditions:

- a shorted, open, or grounded rotor coil
- stator windings shorted, open, or grounded
- rectifier bridge shorted, open, or grounded.

To perform a charging system output test, follow the guidelines in **SKILL DRILL 15-2**.

SKILL DRILL 15-2 Performing a Charging System Output Test

1. Connect a charging system load tester to the battery with the red lead to the positive post, the black lead to the negative post, and the amp clamp around the alternator output wire.

2. Start the engine, turn off all accessories, and measure the regulated voltage at around 1,500 rpm. The regulated voltage is the highest voltage the system achieves once the battery is relatively charged, as evidenced by the ammeter reading less than about 20–30 amps when the amp clamp is around the alternator output cable. Typical regulated voltage specifications are wider than they used to be due to the ability of the electrical system ECM to adjust the output voltage for a wide range of conditions.
3. Operate the engine at about 1,500 rpm and either manually or automatically load down the battery to 12.5 volts or 25 volts for a 24-volt system. Measure the alternator amperage output. This reading should be compared against the alternator's rated output. Normally, the maximum output should be within 10% of the alternator's rated capacity. A hot alternator may have slightly lower results.

► TECHNICIAN TIP

The battery, or battery terminals, should never be removed when the engine is running. Removing battery terminals on alternator-equipped machines may damage the alternator and sensitive electronic equipment fitted to the machine.

► Testing Charging System Circuit Voltage Drop

SI5003

An excessive voltage drop in the charging system output and ground circuit tends to cause one of two problems: (1) The battery is not able to be fully charged because, although the alternator is producing the specified voltage, the voltage drop is reducing the amount of voltage to the battery, or (2) the battery is fully charged, but the alternator is working at a higher

voltage to do so, potentially overheating it. Which of the two issues is occurring depends on where the voltage is sensed. If it is sensed at the alternator, then the battery will generally be undercharged. If the voltage is sensed at the battery, then the alternator will work at the higher voltage. Knowing the system will help you diagnose voltage drop issues in the output and ground circuits of the charging system.

The alternator cable voltage drop test is performed to test the positive cable for excessive resistance between the alternator and the batteries. With the engine running at 1,500 rpm and the alternator loaded to 75% of its output capacity, voltage is measured at the alternator and batteries. If the voltage difference is greater than 0.25 volts in a 12-volt circuit or 0.50 volts in a 24-volt circuit, all positive and ground wire cable connections should be checked. Acceptable cable voltage drop readings are less than 0.25 volts in 12-volt system and 0.50 volts in a 24-volt system. To test charging circuit voltage drop, follow the guidelines in **SKILL DRILL 15-3**.

SKILL DRILL 15-3 Testing Charging Circuit Voltage Drop

1. Set the digital volt-ohmmeter (DVOM) up to measure voltage, and select min/max if available. Connect the red probe of the DVOM to the output terminal of the alternator and the black probe to the positive post of the battery. The red probe goes

on the positive battery post because, in this case, the alternator output terminal is higher voltage than the positive battery terminal. For the meter to read correctly, the leads need to be connected as listed.

2. Start the engine and turn on as many electrical loads as possible or use an external load bank to load the battery. Read the maximum voltage drop for the output circuit.
3. Move the leads to measure the voltage drop on the ground circuit by placing the black probe on the alternator case and the red probe on the negative terminal of the battery. With the engine running and the circuit still loaded, read the maximum voltage drop for the ground circuit.
4. If the measurements are excessive, check each part of the circuit for excessive voltage drops by slowly bringing the probes closer together on each section of the circuit. Determine any necessary actions.

► Inspecting, Repairing, or Replacing Connectors and Wires of Charging Circuits

SI5004

When you are diagnosing charging system problems, you should always make sure you visually inspect connectors and wires of charging circuits for tightness, wear, and damage. Check the connection on the voltage regulator and the alternator for loose electrical connections or shorted wires. Move the wires around while running the engine. If the warning lamp flickers or the ammeter instrument indicates incorrect charging, the problem is in the wire being jarred. You may need to perform a voltage drop test to check wiring along the charging system path. When replacing connectors and/or wires, always refer to the appropriate manufacturer's service manual for the exact procedure. To inspect, repair, or replace connectors and wires of charging circuits, follow the guidelines in **SKILL DRILL 15-4**.

► Removing, inspecting, and Replacing an Alternator

SI5005

During charging system tests, low-voltage and current output problems may indicate a defective alternator. If you find that the alternator is defective, it will need to be replaced. It is the rotors, brushes, stators, rectifier bridges, and cooling fans of the alternator that work together to create magnetic fields, produce current, and charge the system.

Alternators all operate on the same principle. There are, however, differences in their construction and style. Always refer to the appropriate manufacturer's service manual for the

specific type and style of alternator. Follow the manufacturer's instructions when installing a new alternator. To remove, inspect, and replace an alternator, follow the guidelines in **SKILL DRILL 15-5**.

► Overhauling an Alternator

SI5006

Overhauling an alternator requires the disassembly and checking of all component parts. The alternator component parts should also be cleaned and replaced or repaired as necessary. The alternator is relatively simple to disassemble. You should always mark the position of the housings in relation to each other before commencing disassembly. This ensures that the housings are correctly aligned when reassembled.

Most alternators have the brushes inside the alternator, and they cannot be removed until the alternator is disassembled. However, some alternators have a brush box, which should be removed before the alternator is disassembled. Before commencing disassembly, check to see if the brushes can be removed while the alternator is in one piece. If so, undo the brush box and remove it. To disassemble the alternator, remove the through bolts with a suitable wrench or socket. Pry the housings apart; this may require a small pry bar to separate apart the housings, as they are usually a tight fit. When prying the housings apart, be careful not to damage any of the stator windings. The rotor will usually be attached to the pulley end housing. Once the alternator is separated into its two housings, further disassemble the alternator into its component parts. This may require the use of a soldering iron to remove the rectifier diodes and the brushes. The rectifier and main battery terminals will have a number of insulating bushings fitted to them. Be sure to note how the insulators are fitted for later replacement.

SKILL DRILL 15-4 Inspecting, Repairing, or Replacing Connectors and Wires of Charging Circuits

1. Locate and follow the appropriate procedure and wiring diagram in the service manual.
2. Move the equipment into the shop, apply the parking brakes, and chock the equipment's wheels. Observe lockout and tag-out procedures.

3. If the machine has a manual transmission, place it in "neutral." If it has an automatic transmission, place it in "park" or "neutral."
4. Trace the wiring harness from the alternator to the battery and around the engine bay.
5. Check the harness and connectors for wear, damage, and corrosion.
6. Disconnect the battery negative cable if repairs are necessary.
7. Repair damaged areas with replacement cables or connectors. Ensure all harnesses are secured to prevent abrasion or damage from vibration.
8. Reconnect all harness plugs and secure all connections.
9. Reconnect the battery negative cable.
10. Check the repair with a visual inspection and by running the machine.
11. Clean the work area and return tools and materials to their proper storage area.

SKILL DRILL 15-5 Removing, Inspecting, and Replacing an Alternator

1. Locate and follow the appropriate procedure in the service manual.
2. Move the machine into the workshop or safe work area, apply the parking brakes, and chock the machine wheels. Observe lockout and tag-out procedures.
3. If the machine has a manual transmission, place it in "neutral." If it has an automatic transmission, place it in "park" or "neutral."

4. Disconnect the battery from the machine.
5. Disconnect wires at the connector on the alternator. Make a note of the location and any special insulating washers.
6. Loosen bolts.
7. Slide the belt off the alternator.
8. Lift the alternator out of machine.
9. Place a new alternator onto the engine.
10. Hand screw the bolts without tightening; connect wires first if needed.
11. After checking the condition of the belt and replacing it if needed, slip the belt on each pulley and properly align the belt grooves with the alternator pulley grooves.
12. If required, adjust belt tension using a belt tension gauge.
13. Tighten the bolts.
14. Reconnect the battery.
15. Start the engine and verify that the alternator is charging.
16. Clean the work area and return tools and materials to their proper storage area.

Once the alternator has been disassembled into its component parts, conduct the following tests for each component:

- Housings
 - Clean and check housings for cracks. If they are damaged, replace them.
- Rotor
 - Check the resistance of the winding against the manufacturer's specifications. In some cases, it is also useful to check the current draw of the winding. Remember, the winding is inductive. This means it will produce a spark when power is connected or disconnected.
 - If the alternator has slip rings, check them for mechanical wear. If they are excessively worn, the slip ring assembly will need to be replaced. To do this, remove the coil wires and press off the old slip ring. Press on a new slip ring and reconnect the coil wires. You may need to machine a new slip ring in the lathe to produce a clean, round finish.
 - Check bearing surfaces and pulley retaining thread for wear. Replace the rotor if they are excessively worn.
- Diode rectifier
 - Check the diode rectifier with a diode checker. You can use a DVOM; however, a specialized alternator diode tester is recommended because it places a load on the diodes. Replace diodes if they fail the test. In some cases, individual diodes can be replaced. In others, the whole rectifier must be replaced as a unit.
- Regulator
 - Use a regulator tester to check the regulator. Each regulator tester is slightly different, although they perform

the same job. Always check the manufacturer's specifications for the correct connections and procedure. Modern regulators are electronic and generally cannot be repaired. Replace the regulator if required.

- Brushes
 - If fitted, brushes should be replaced whenever the alternator is overhauled. Take care when reassembling the alternator to ensure the brushes are not damaged. Many alternators require the insertion of a pin to hold the brushes away from the slip rings as the alternator is reassembled.
- Bearings
 - Bearings should be replaced whenever the alternator is overhauled.
- Pulley and fan
 - Check the pulley and fan for wear, and replace it if necessary. When replacing the fan, ensure that it is replaced with one that operates in the same direction as the one removed.

Once the alternator has been overhauled, you will need to test it in an alternator test bench. Clamp the alternator securely in the test bench and make the electrical connections. Pay particular attention to the battery, regulator, and warning light to ensure they are connected as per the manufacturer's specifications. Run the alternator up to speed and make sure the warning light operates correctly, the alternator can generate its specified maximum current output, and the regulated voltage is within specifications. To overhaul an alternator, follow the guidelines in **SKILL DRILL 15-6**.

SKILL DRILL 15-6 Overhauling an Alternator

1. Locate and follow the appropriate procedure in the service manual.
2. Check to see if the brushes need to be removed first. If so, remove the brush box or regulator.
3. Remove the through bolts holding the alternator together.

4. Pry the alternator apart.
5. Disassemble the component parts from the housing. Take note of the placement of insulator bushes.
6. Clean, test, and inspect all component parts. Use specialized testers where necessary—for example, regulator tester, diode tester, and DVOM.
7. Replace any faulty components. If the slip ring assembly requires replacement, ensure the new slip ring is machined on the lathe.
8. Reassemble component parts into the housings.
9. Reassemble the alternator housings. Ensure the brushes are retained using a retaining pin to prevent damage to them.
10. Test the alternator in the alternator test bench. Ensure the warning light circuit is working and test for maximum current output and voltage regulation.
11. Clean the work area and return tools and materials to their proper storage.

Wrap-Up

Ready for Review

- ▶ Both DC generators and alternators produce electricity by relative movement of conductors in a magnetic field. The key difference between an alternator and a DC generator is which component rotates or moves to generate electricity.
- ▶ The charging system provides electrical energy for all of the electrical components on the equipment. The main parts of the charging system include the battery, the alternator, the voltage regulator (which may be integrated into the alternator), a charge warning light or voltmeter, and wiring that completes the circuits.
- ▶ The alternator converts mechanical energy into electrical energy by electromagnetic induction.
- ▶ A single-phase stator has a single winding, which creates a single sine wave. In a typical equipment alternator, there are three separate coils of wire composing the stator.
- ▶ Alternators have a built-in maximum current limitation due to the CEMF in the stator coils.
- ▶ Brushless alternators have greater longevity than alternators with brushes.
- ▶ Alternators require an initial magnetic field to be produced within the rotor to initiate the process of generating electricity. Initial excitation can be either internal or external.
- ▶ Wye and Delta windings produce three-phase AC current, but voltage and amperage outputs differ according to speed and load. The Wye configuration produces higher voltage at lower rotor speeds.
- ▶ Alternators are much more efficient at producing current than DC generators are. Alternating current—not direct current—is produced inside an alternator.
- ▶ To change AC to DC, automotive alternators use a rectifier assembly consisting of two diodes for every phase of the stator winding.
- ▶ Alternators' voltage output is controlled by a voltage regulator. The voltage regulator regulates current output and limits the maximum charging system voltage.
- ▶ A significant amount of heat is produced within the alternator from the rectifier, stator, and rotor windings.
- ▶ Alternators can be driven by a pulley or direct drive through a gear.
- ▶ Equipment having high-current loads at idle or those with extra electrical loads can use two or more alternators.
- ▶ When diagnosing charging system problems, always start with the battery. A weak or dead battery, corroded battery-cable connections, and/or damaged or worn components may cause a no-crank or slow-crank problem.

Key Terms

AC ripple A pattern produced by voltage fluctuations from the alternator that create differences between the peak voltage of an AC sine wave and the minimum voltage found in the trough between sine waves.

alternator ripple The top of the waveform.

delta windings Stator windings in which the windings are connected in the shape of a triangle.

full fielding Making the alternator produce maximum amperage output.

load-dumping A feature that allows temporary suppression of high-voltage spikes.

overrunning alternator decoupler (OAD) A pulley that uses an internal spring and clutch system that allows it to rotate freely in one direction and provide limited, spring-like movement in the other direction.

rectification A process of converting alternating current (AC) into direct current (DC).

remote sensing Referencing the battery positive connection through an input terminal that is used for the regulator reference voltage.

residual magnetism The small amount of magnetism left on the rotor after it has been initially magnetized by the coil windings' magnetic field.

self-exciting alternator An alternator that relies on the residual magnetism found in the rotor after operating as a way to switch on the voltage regulator and supply current to the rotor.

sensing The voltage reference point the alternator uses for regulation of the output.

transient voltage suppression (TVS) diodes Specialized diodes in the rectifier bridge that become resistive rather than conductive at a specific voltage level.

wye windings Stator windings in which one end of each phase winding is taken to a central point where the ends are connected together.

Review Questions

- Which of the following are functions of the battery?
 - It stores an electrical charge in chemical form.
 - It acts as an electrical dampening device for variations in voltage or voltage spikes.
 - It provides the electrical energy for cranking the engine.
 - All of the choices are correct.
- Which of the following are correct concerning alternator principles?
 - The alternator converts mechanical energy into electrical energy by electromagnetic induction.
 - In a simplified version, a bar magnet rotates in an iron yoke, which concentrates the magnetic field.
 - A coil of wire is wound around each end of the yoke; as the magnet turns, voltage is induced in the coil, producing a current flow.
 - All of the choices are correct.
- Which of the following is NOT an alternator classification?
 - Externally air cooled
 - Water cooled
 - Sealed
 - None of the above
- Between _____ and _____ pole pieces or "claws" are found in the rotor of equipment alternators.
 - 4; 8
 - 8; 12
 - 12; 16
 - 18; 22
- Which of the following is correct concerning phase winding connections?
 - As the name suggests, Wye windings resemble the letter "Y."
 - The advantage of Wye windings is that they produce higher voltage at comparably lower rotor speeds.
 - This advantage means the alternator can begin charging a battery at lower engine speeds.
 - All of the choices are correct.
- Which of the following is correct concerning rectifier diode problems?
 - Heat can cause premature failures of diodes.
 - Additional cooling of rectifier bridges can be accomplished with heavier diodes and heat sinks or by connecting diodes in parallel so that six rather than three pairs accomplish the work.
 - Both a and b
 - Neither a nor b
- Which of the following is correct concerning smoothing capacitors?
 - Capacitors can be used to smooth alternator AC ripple and prevent EMI.
 - In the alternator, one is connected across the output to act like an electric shock absorber.
 - When the output voltage increases slightly, the capacitor will charge and absorb the new increase.
 - All of the choices are correct.
- Which of the following charging system set points is optimal for a 12-volt system?
 - 12.6 to 12.9 volts
 - 13.0 to 13.4 volts
 - 13.5 to 14.6 volts
 - 14.1 to 15.1 volts
- Which of the following features does a remote sensing alternator use?
 - An external voltage regulator
 - A voltage regulator with an "R" terminal connected to the stator winding
 - A direct connection between the battery and the voltage regulator
 - A dash-mounted voltage regulator to indicate charging system output
- Vents within the frames provide for a _____ amount of airflow to assist in dissipating heat.
 - large
 - steady
 - small
 - barely perceptible

ASE Technician A/Technician B Style Questions

- Technician A says that today, the average 12-volt electrical system loads for a late-model machine add up to as much as 150 amps at peak load. Technician B says that both DC

generators and alternators produce electricity by relative movement of conductors in a magnetic field. Who is correct?

- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says that alternators have more moving parts than they have generators. Technician B says that alternators can produce power at engine idle speeds; generators cannot. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says that the two most important parts in an alternator used to produce electrical current are the rotor and stator winding. Technician B says that the rotor contains a spinning electromagnet that induces current flow in the stator winding, which is made up of numerous coils of wire. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
4. Technician A says that the rotor is a rotating electromagnet field that cuts the wire coils within the stator to induce the flow of electrical current in the stator. Technician B says that the direct-gear drive mechanism is used in most cases but that a pulley drive may also be employed. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says that regulated current to the alternator rotor is supplied through a pair of graphite brushes sliding against slip rings on the rotor shaft. Technician B says that heavy-duty springs help the brushes maintain contact with the slip rings. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
6. Technician A says that machines fitted with self-exciting alternators may require the engine rpm to be briefly

increased after every start-up to initiate charging. Technician B says that using self-exciting alternators eliminates the need for a separate circuit from the key switch to the alternator and simplifies chassis wiring. Who is correct?

- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
7. Technician A says that the stator is mounted between two end housings, and it holds the stator windings stationary so that the rotating magnetic field cuts through the stator windings, inducing an electric current in the windings. Technician B says that to smooth the pulsating current flow, there are three distinct layers of windings offset 60 degrees in each layer from one another. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says that stators are normally serviced in a repair facility. Technician B says that stators can be visually checked during rebuilding for burned, cut, or nicked winding laminations. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
9. Technician A says that alternators produce alternating current, which can be used to operate many onboard electrical devices. Technician B says that converting the AC current to usable DC current is referred to as modulation. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
10. Technician A says that voltage regulators are first classified as either external or internal. Technician B says that the majority of late-model alternators have external regulators. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

CHAPTER 16

Electrical Sensors, Sending Units, and Alarm Systems

Knowledge Objectives

After reading this chapter, you will be able to:

- **K16001** Identify and describe the functions, construction, and application of electronic sensors used to produce electrical signals for machine electronic control systems.
- **K16002** Identify and describe the operating strategies of electronic signal processing systems used in electrical system control on mobile heavy equipment.
- **K16003** Recommend and describe diagnostic procedures for sensors used in electronic control systems.

Skills Objectives

After reading this chapter, you will be able to:

- **S16001** Perform diagnostic procedures to evaluate the condition and operation of machine sensors, sending units, and warning systems.
- **S16002** Select and use the appropriate test instruments for evaluating the operation of sensors, sending units, and alarm systems.

► Introduction

Devices that convert one form of energy into another are called transducers. Sensors are a type of transducer that convert physical conditions or states into electrical data. Pressure, temperature, angle, speed, mass, etc. are just a few of the changing physical variables about which sensors supply electrical data to processors. A distinction is made between sending units and sensors. Sensors provide information to electronic control units, whereas sending units provide information to instrument gauges.

► Types of Sensors

K16001

An enormous number of sensor types exist to measure diverse types of data required by increasingly sophisticated machine management systems:

- accelerometers for machine dynamic control
- pressure sensors for engine oil, fuel, crankcase, and intake boost
- position sensors for machine speed, camshafts, crankshafts, and pedal position
- humidity sensors for adjusting air–fuel ratio control and cabin comfort control
- sunlight and rain/moisture sensors
- distance sensors for near obstacle detection and collision avoidance
- magnetoresistive (MR) sensors that use the earth's magnetic field to operate machine electronic compasses and navigation systems
- torque sensors
- fuel level sensors
- oil quality sensors
- temperature sensors
- coolant level sensors
- barometric pressure sensors
- mass airflow sensors
- engine knock sensors
- exhaust gas—NOx, ammonia, and oxygen sensors
- yaw sensors using the Coriolis effect to sense yaw rates
- global positioning sensors for GPS.

Active Versus Passive Sensors

All the types of sensors listed above are more simply classified other ways. For example, a sensor is considered active or passive depending on whether they use power supplied by the electronic control module (ECM) to operate. **Active sensors** use a current supplied by the ECM to operate while **passive sensors** do not (**FIGURE 16-1**).

Other classifications of sensors include the following:

- resistive sensors: rheostats, potentiometers, thermistors, piezoresistive sensors, and Wheatstone bridge pressure sensors
- voltage generators: oxygen sensors, NOx sensors, ammonia sensors, variable reluctance sensors, and piezoelectric sensors
- switches
- variable capacitance pressure sensors.

FIGURE 16-1 This opened pressure sensor is an active sensor. Note the integrated circuit used to change the sensed physical data into an electrical signal used by the ECM.

You Are the Mobile Heavy Equipment Technician

A customer has brought a wheel loader to your shop, complaining that the engine will occasionally not accelerate. Sometimes, after the throttle pedal is pushed multiple times, the engine will only idle. Other times the engine drops to idle while the machine is moving. Sometimes the problem corrects itself after the ignition key is cycled; other times the throttle starts operating correctly on its own. After checking for fault codes, you learn the machine has had codes erased by another technician. You suspect the problem is in the accelerator position sensor (APS), but you wonder if the problem could be in the wiring or the fuel system, or if it's a power derate condition caused by some other fault. After carefully inspecting the wiring harness and connectors to the APS, you believe they are in good condition. You connect a software-based diagnostic program to the machine data link to monitor the APS. There are three APS signals displayed with different voltages on each sensor. Consider the following questions as you proceed:

1. Does this APS use an idle validation switch?
2. What complaint would the operator have if one, two, or three of the APS voltages were incorrect?
3. How will you determine if the APS has a fault?

Reference Voltage

Reference voltage (V_{ref}) refers to a precisely regulated voltage supplied by the ECM to sensors. Reference voltage value is typically 5 volts direct current (VDC), but some manufacturers use 8 or 12 volts. The use of a reference voltage is important in processor operation, because the value of the variable resistor can be calculated by measuring voltage drop when another resistor with a known voltage input is connected in series with it. In **FIGURE 16-2**, 5 V_{ref} is used in the calculations performed by an ECM.

Reference voltage also supplies active sensors with current to operate integrated circuits contained inside the sensor. Switches will also use +5 V_{ref} to signal the ECM.

Switches as Sensors

Switches are the simplest sensors of all, because they have no resistance in the closed position and infinite resistance in the open position. Switches are categorized as sensors whenever they provide information to an electronic control system. The data may indicate a physical value such as open or closed, up or down, high or low (e.g., a coolant level sensor or oil pressure switch), or it may indicate on and off (e.g., a brake light switch).

Switches as Digital Signals

The simplest digital signal is a single pole, single throw (SPST) switch. It is found in either an open or closed state. The on/off, open/closed state data provided by this switch can provide input information to an ECM required for decision-making. For example, the decision to start an engine based on whether a transmission is in neutral or the clutch is disengaged depends on the signal from a switch (**FIGURE 16-3**). A zero-volt signal

would present as an open switch, while 12 volts would present as a closed switch. Ignition, brake, or door switches provide similar data to ECMs to answer simple yes or no, open or closed, on or off questions posed by operating software.

Pull-Up and Pull-Down Switches

Switches are further categorized by their connection to a current source and the ECM. When the switch is connected between the ECM and a battery positive, the switch is known as a **pull-up switch** (**FIGURE 16-4**).

Reference voltage also supplies active sensors with current to operate integrated circuits contained inside the sensor. Switches will also use +5 V_{ref} to signal the ECM.

A circuit inside the module that is monitoring the switch connection will measure the voltage drop across a fixed resistor inside the ECM. The voltage data will provide information to processing circuits, which will determine whether the circuit or switch is open, closed, out of range, or shorted to ground.

A **pull-down switch** is connected between the ECM and a negative ground current potential (**FIGURE 16-5**).

When the switch is closed, ground current will flow into the ECM. A circuit inside the ECM monitoring the switch connection will also measure voltage drop across a fixed resistor. Once again, voltage data will provide information to processing circuits, which will determine whether the circuit or switch is open, closed, out of range, or shorted to a positive current potential.

Resistive Sensors

Resistive sensors are a class of sensors that will condition or change a voltage signal applied to the sensor. Many types of

FIGURE 16-2 Reference voltage is supplied to power active sensors and to accurately calculate voltage drop across the sensor. The resistor in series with the reference voltage also limits current to the sensors.

FIGURE 16-3 Examples of some basic switched inputs: clutch, brakes, power take-off, and proximity sensor switches.

FIGURE 16-4 When a positive polarity is switched and supplied to the ECM, it is referred to as a pull-up switch.

FIGURE 16-5 When a negative polarity is switched and supplied to the ECM, it is known as a pull-down switch.

resistive sensors exist, and pressure, temperature, and position sensors are the most common. Some of these sensors are three-wire active sensors.

Thermistors

A **thermistor** is a temperature-sensitive variable resistor commonly used to measure coolant, oil, fuel, and air temperatures. The name itself combines the words thermal and

resistor. Thermistors are two-wire sensors that change resistance in proportion to temperature. This means thermistors provide analog data to processing circuits. When the sensor is measuring air temperature, such as in an intake manifold, the sensor is often constructed with a plastic body to minimize heat transfer from surrounding metal. When used to measure coolant or oil temperatures, the sensor element is enclosed in a brass case to make it more responsive to temperature change (**FIGURE 16-6**).

Thermistors are semiconductor devices with no moving parts. Two types of thermistors exist: negative temperature coefficient and positive temperature coefficient. In a negative temperature coefficient (NTC) thermistor, the resistance decreases as the temperature increases (**FIGURE 16-7**). In a

FIGURE 16-6 Three thermistor applications. **A.** For intake manifold temperature. **B.** For coolant temperature. **C.** For intake manifold temperature. Note the semiconductor material in the fast response, air-intake thermistor.

FIGURE 16-7 A thermistor circuit. Note the graph that illustrates the relationship between temperature and resistance.

FIGURE 16-8 Thermistors found in A. diesel particulate filters (DPFs) and B. selective catalyst reduction systems are often C. PTC thermistors. NTC thermistor material could not withstand the heat encountered when regenerating the DPF.

positive temperature coefficient (PTC) thermistor, the resistance increases as the temperature increases (**FIGURE 16-8**).

The most common type of thermistor is an NTC, in which the sensor's resistance goes down as the temperature goes up.

So, when the sensor is cold, the sensor resistance is high and the ECM measures a lower return signal voltage in comparison to reference voltage. The voltage drop across the sensor is interpreted as a temperature value. Likewise, when the engine warms, the internal resistance of the sensor decreases and causes a proportional increase in the return signal voltage.

Rheostats

Rheostats are also two-wire variable resistance sensors. They are not commonly used as input devices to an ECM but are instead used to signal sending units such as for fuel level and oil pressure (**FIGURE 16-9** and **FIGURE 16-10**).

Rheostats use a variable sliding contact moving along a resistive wire. When current passes through the resistive wire, the sliding contact will conduct current flow from the wire. Current intensity at the sliding contact will vary depending on its position along the resistive wire.

Reference Voltage Sensors—Three-Wire Sensors

Three-wire sensors, regardless of how they appear or what function they perform, have a common wiring configuration: they all have ground, signal return, and positive voltage reference wire leads (**FIGURE 16-11**).

FIGURE 16-9 Operation of a rheostat controlling the intensity of a lightbulb.

FIGURE 16-10 A rheostat for a fuel level sending unit. The wiper-whiskers transfer current from one resistive track to another. Signal return is supplied by the wipers.

One wire provides reference voltage to the sensor. If it is an active sensor, reference voltage will supply current to operate an integrated chip inside the device. Reference voltage is also produced by the ECM as a comparison point for voltage calculations associated with sensor data.

The second sensor wire provides a negative ground signal through the ECM and not to engine ground. This ECM return or ground is also called zero-volt return (ZVR) and is identical to engine ground except that it is free of any type of electrical interference. Active sensors will use the ZVR or negative ground for the other source of current to operate the

FIGURE 16-11 Three-wire reference voltage sensors have a ground, signal return, and positive voltage reference wire lead.

sensor. In resistive sensors, the ZVR acts as a reference point to measure voltage drop across the sensor.

The third wire is a signal return from the sensor. This circuit provides a positive voltage proportional to the physical value measured by the sensor. If pressure is the physical input measured, the signal wire data will carry an analog voltage signal proportional to pressure. Typically, low voltage of, for example, 0.8 volts will represent little to no pressure, while 3.9 volts will represent high pressure depending on the range of the sensor.

The advantage of using three-wire sensors is that they provide comprehensive diagnostic information about the sensor and its circuit operation. Sending units can be constructed with reduced complexity and expense and yet still provide the ECM with data to operate an engine, transmission, or other device. However, sending units lack the capability to self-monitor circuit operation. Consider an open or shorted to ground signal wire from a single-wire sensor. In this case, there is no means by which the ECM could accurately evaluate the situation. The wire could be broken or rubbed through, and still the unit voltage data received by the ECM would not be different from normal. It is very labor-intensive to find an electrical fault based on only an operational symptom—no fault codes or malfunction indicator lights are available to identify a circuit problem.

The ECM does have capabilities to monitor and diagnose two- and three-wire sensor circuits to an extent not possible with single-wire sensors. By monitoring the voltage range of the ground return path, signal voltage, and reference voltage, the ECM can determine whether the sensor and circuit are functioning correctly (**FIGURE 16-12**).

Sensor values can be compared with expected values to determine whether the data is rational. An explanation of how sensors and electronic circuits perform self-diagnostics and generate codes is covered in the Onboard Networks & Diagnostics Systems chapter.

FIGURE 16-12 The ECM supplies the +5 Vref and ZVR ground. In this sensor, the ECM measures voltage between the + signal return and ZVR.

Potentiometers

Potentiometers are similar to rheostats in that they vary signal voltage depending on the position of a sliding contact or wiper moving across a resistive material. They are three-wire sensors with the signal wire connected to the internal wiper. Potentiometers supply analog data to processing circuits.

A common application of a potentiometer is a position sensor such as the throttle position sensor (TPS) (**FIGURE 16-13**).

This sensor is connected to a throttle pedal, lever, or dial and provides data regarding the operator's desired engine speed or power output by measuring pedal, lever, or dial angle or travel. The ECM will measure the voltage drop between the ground return circuit and the signal wire to calculate pedal, lever, or dial position. Voltage produced from the signal wire will be proportional to the pedal travel. This means that at

idle or part throttle, the voltage at the signal wire will be low. Increasing pedal travel will produce increasing voltage to the signal wire as the sensor's internal wiper moves closer to the +5 Vref end of the resistive element. When the pedal returns to idle, the wiper will have less voltage because it is farther away from the +5 Vref wire and because the current pathway is longer and therefore more resistive.

Idle Validation Switches and Throttle Position Sensors

A short circuit or incorrect data from the TPS, also called the accelerator position sensor (APS), can potentially cause the uncontrolled acceleration of an engine. For safety reasons, manufacturers will build an additional safety system to verify throttle position. One common throttle safety system is the **idle validation switch (IVS)**. This circuit uses two switches: at idle, one switch will be open and the other closed. Off idle, the switches change state, which means that the normally open switch closes and the normally closed switch opens (**FIGURE 16-14**).

This data is used by the ECM to verify that the operator has in fact moved the accelerator pedal and that the circuit is not malfunctioning. At idle, the state of the switch must correspond to the TPS voltage sensed by the ECM. If the expected position sensor voltage and IVS position do not match, the ECM will revert engine speed to idle or not allow the engine rpm to increase beyond idle speed.

Dual- and Multiple-Path Throttle Position Sensors

To improve the reliability of a TPS and validate accelerator position signals, some manufacturers are replacing the single

FIGURE 16-13 The TPS circuit commonly uses a potentiometer to measure throttle angle.

Integrated Sensor Plug

Sensor Schematic

FIGURE 16-14 The IVS is usually integrated with the TPS. The IVS uses reference voltage and will switch the state of a normally open and a normally closed switch when moved off idle. **A.** Three sensor wires (A), three IVS wires (B), and the throttle position sensor (C). **B.** Color coding for integrated sensor plug.

TPS sensor track with a dual-track or even three-path TPS. The voltage of one sensor pathway is compared with another to verify that the sensor is operating within expected values (**FIGURE 16-15**).

If there is an unexpected difference between the voltage signals, the engine will only operate at idle speed. If one or even two of the resistive tracks wears out, the engine may still accelerate normally, but an APS fault is logged and the yellow fault warning indicator lamp will illuminate. Dual-path TPSs are potentiometers. Hall-effect TPSs are even more reliable because they have no moving parts. This TPS uses an alternating current (AC) magnetic field to induce current in a rotor moved by the throttle pedal. A circuit is used to convert the rotor's position into pedal position. This type of noncontact TPS sensor has no sliding friction parts to wear out (**FIGURE 16-16**).

FIGURE 16-15 Voltages of accelerator position for the three-path sensor. Operating voltages are different for any given throttle angle. If one sensor fails, the other can supply a signal to operate the machine. If two signals fail, the machine will typically be only idle.

FIGURE 16-16 Hall-effect throttle position sensor (TPS). **A.** Conductive lamps in rotor. **B.** Integrated circuits, APP1 and APP2. **C.** Electromagnetic field lines of force. **D.** Stator excitation coils. **E.** Stator receiver coils.

Pressure Sensors

Pressure measurements, such as intake manifold boost, barometric pressure, and oil and fuel pressure, use two types of sensor technology: variable capacitance sensors and strain gauge resistive sensors. These are both active sensors that produce analog output signals.

Strain Gauges

A strain gauge measures small changes in the resistance of tiny wires caused by stretching or contraction. Construction of this type of pressure-sensing device uses resistive wires, called strain gauge wires, embedded in a flexible glass block. Behind the block may be a vacuum chamber to provide a reference point of zero for measurement of absolute pressure. If the device measures gauge pressure, the chamber will have atmospheric pressure as the reference value of zero.

When the glass plate flexes under pressure, the small resistive wires in it will change dimensions slightly. As the plate distorts due to pressure changes, it changes the resistance of the wires slightly (FIGURE 16-17).

FIGURE 16-17 A strain gauge senses pressure via a wire embedded in glass or metal film that changes resistance as it is stretched under pressure.

A Wheatstone bridge electrical circuit, which measures changes in resistance of an unknown variable resistor, is used to measure this small change in resistance of the strain gauge wires (FIGURE 16-18).

By measuring this small change in the wires' resistance, the pressure applied to the plate is determined.

Piezoresistive Sensors

Piezoresistive sensors rely on the ability of certain mineral crystals to produce voltage or change resistance when compressed (FIGURE 16-19).

Rather than using a strain gauge wire construction, these sensors have a piezoresistive crystal arranged with a Wheatstone bridge to measure the change in resistance of the piezo crystal. These sensors produce analog electrical signals.

The advantage of these sensors is their ability to measure very high pressures. Because of the sturdiness of the crystal, piezo sensors are better adapted to measuring vibration and dynamic or continuous pressure changes. Knock sensors measuring abnormal combustion signals are a common application of piezoresistive

FIGURE 16-19 The piezoresistive principle.

FIGURE 16-18 A Wheatstone bridge calculates the value of an unknown resistor using several other resistors of known fixed value.

FIGURE 16-20 Construction of a silicon-based piezoresistive sensor. The silicone-ceramic material generates a voltage under pressure that is converted to an analog signal.

sensors. Another type of piezoresistive sensor uses mineral crystals arranged on a substrate of silicon (**FIGURE 16-20**).

The crystals behave as a semiconductor to produce electrical signals that are amplified and conditioned by internal circuits. Silicon-based piezoresistive sensors are very sensitive to slight pressure changes.

Variable Capacitance Pressure Sensor

A **variable capacitance pressure sensor** is an active sensor that measures both dynamic and static pressure. Though they are more expensive to manufacture than a piezoresistive or strain gauge sensor is, the variable capacitance pressure sensor offers a greater range of measurement flexibility and more accurate readings. Because it is an active sensor, the stronger circuit signals to the ECM are not as vulnerable to voltage drop or electromagnetic interference.

Variable capacitance sensors use the distance between two plates, or dielectric strength, inside the sensor to measure pressure (**FIGURE 16-21**).

One plate diaphragm will move in response to intake manifold, oil, fuel, or some other physical pressure being measured. The other plate is fixed and has on one side a reference vacuum or pressure chamber to calibrate it for accurate pressure readings. As pressure increases or decreases, the distance between the two plates will change. An electrical charge is applied to the fixed plate, and the time it takes to charge the plate is measured. Charging time will change proportionally to the dielectric strength between the plates. An electronic circuit in the chip integrated inside the sensor measures the changing voltage/time value produced by the flexing plate and outputs an analog electrical signal of less than 5 volts.

FIGURE 16-21 Cross section of a variable capacitance sensor.

Voltage Generators

This category of sensors is passive and produces an analog signal of varying voltage or AC frequency. Variable reluctance and galvanic sensors are two examples of voltage-generating sensors. While the gas sensors used on today's diesel engines are active sensors with modules that produce and condition signals, the operating principle is still a galvanic reaction that produces voltage. Exhaust stream gas sensors are used to measure oxygen, NO_x, or ammonia gases in the exhaust stream. On diesel engines, data from oxygen sensors is commonly used to adjust exhaust gas recirculation (EGR) rates and sometimes to adjust the intake throttle plate position to control the operation of exhaust after treatment systems. Ammonia and NO_x sensors are used to identify faults in the exhaust after treatment systems on most diesels from 2010 and later. Ammonia sensors are more frequently used on diesel engines from 2015 and later.

Variable Reluctance Sensors

Variable reluctance sensors are two-wire sensors used to measure rotational speed. Wheel speed, machine speed, engine speed, and camshaft and crankshaft position sensors are their most common applications (**FIGURE 16-22**).

Signals from the camshaft and crankshaft position sensors are used to calculate engine position for determining the beginning of engine firing order and injection timing. The camshaft gear has raised lugs that generate waveform signals to identify top dead center (TDC) for each cylinder. When graphed against time, the AC waveform produced by the sensor data is used to precisely calculate not only engine speed but also degrees of crankshaft rotation (**FIGURE 16-23**).

The ability of a material to conduct or resist magnetic lines of force is known as reluctance. Variable reluctance sensors use changing sensor reluctance to induce current flow by changing

FIGURE 16-22 Common applications of variable reluctance sensors.

FIGURE 16-23 The tooth geometry of the crankshaft and camshaft sensors generates unique waveforms that identify cylinder-firing position and crank position.

FIGURE 16-24 The reluctor ring helps the variable reluctance sensor generate an AC voltage signal.

magnetic-field strengths inside the sensor. A variable reluctance sensor is constructed with two main elements: a coil of narrow-gauge wire wrapped many times around a permanent magnet, and a reluctor ring (also called the sensor wheel, pulse wheel, or tone wheel), which has soft iron teeth and rotates on a shaft (**FIGURE 16-24**).

Because ferrous metals, particularly soft iron, have low reluctance and air has high reluctance to magnetic lines of force, the strength of the sensor's magnetic field expands and collapses as the reluctor ring's iron teeth pass across the sensor's magnet. By changing the density of magnetic lines of force, alternately expanding and contracting the magnetic field when a gear tooth or gap passes by the sensor, current is induced in the wire coil around the sensor magnet. Increasing reluctor wheel speed increases the voltage induced in the sensor. A small air gap of approximately 0.02–0.03 inch (0.51–0.76 mm) is maintained between the sensor and the reluctor wheel. Too much or too little air gap will prevent the sensor from detecting tooth movement. Software inside the ECM will detect and count the number of teeth passing by the sensor to calculate shaft speed.

If the processing circuits track how many teeth complete one rotation of the shaft, rpm is easily calculated. If the engine software can divide the number of teeth passing by the sensor per unit of time, it can precisely calculate the number of degrees of crankshaft rotation.

Hall-Effect Sensors

Like variable reluctance sensors, **Hall-effect sensors** are commonly used to measure the rotational speed of a shaft. Though they are more complex and expensive to manufacture than variable reluctance sensors are, Hall-effect sensors have the advantage of producing a digital signal square waveform and have strong signal strength at low shaft rotational speeds. This is especially useful when cranking an engine when engine rpm is slow. The durability and accuracy of the digital signal is preferred when more precise injection event timing is necessary, which is why most engines today use Hall-effect sensors.

The operation principle of a Hall-effect sensor is simple: Current flow through a Hall-effect material is made from semi-conductive material that changes resistance in the presence of a magnetic field (**FIGURE 16-25**).

When current is applied to a Hall-effect material, no conduction occurs. However, in the presence of a magnetic field, the material will conduct current. The electrical signal output from the sensor material is analog, but circuits within the sensor will convert and amplify the rising and falling voltage into a square-shaped electrical waveform (**FIGURE 16-26**).

To produce the signal from the Hall-effect sensor, two configurations are used. The most common arrangement is the use of a metal interrupter ring or shutter and a permanent magnet positioned across from the sensor. Because ferrous metals have a lower magnetic reluctance than air, magnetic lines of force from a magnet placed opposite the sensor will flow through the metal shield rather than the sensor. Gaps in the interrupter ring will allow magnetism to penetrate the sensor, changing current flow through the Hall-effect material. Attaching the interrupter ring to a moving shaft provides rotational speed information to the control module. Another configuration for the Hall-effect sensor incorporates the magnet into the sensor itself. When a gear tooth or other ferrous metal trigger is present near the sensor, the magnetic field expands. Movement of the ferrous trigger or tooth away from the magnet causes magnetic-field contraction. This pulsing magnetic field generates the signal within the sensor (**FIGURE 16-27**).

FIGURE 16-25 Hall-effect material is semiconductive and its ability to conduct electrical current changes in the presence of a magnetic field.

FIGURE 16-26 Comparing the signals of a Hall-effect sensor and variable reluctance sensor.

FIGURE 16-27 Operation of a camshaft position Hall-effect sensor using an internal permanent magnet.

Oxygen Sensors

Oxygen sensors are used to measure air–fuel ratio in order to calibrate EGR flow rates and air–fuel ratios for exhaust after treatment devices. Diesel engines use a heated planar, wide-band, zirconium-dioxide (ZrO_2) dual-cell oxygen sensor. This sensor technology is different from the narrow-band oxygen sensor technology used commonly on gasoline engines operating at stoichiometric air–fuel ratios. Wide-band oxygen sensors are used in diesel engines because they use lean-burn combustion systems, which normally leave an excess of air in the exhaust. Rather than producing a sharply falling and rising voltage near 0.5 volts, with 2% exhaust oxygen content found in gasoline engines, wide-band sensors produce a voltage proportional to a widely varying oxygen level (**FIGURE 16-28**).

The type of ceramic sensing element commonly used by wide-band sensors is a platinum-coated oxide of zirconium (ZrO_2). An important property of this ceramic is that it conducts oxygen ions when voltage is applied at high temperatures.

Diesel oxygen sensors are **wide-range planar sensors**, which means the sensing element is flat rather than thimble-shaped—that is, thimble-shaped like the sensors used on older gasoline-fueled engines (**FIGURE 16-29**).

They are also wide-band sensors, which means they generate a signal with a wide air–fuel ratio between 0.7:1 and infinity. When heated to over 1,200°F (700°C), the sensor becomes electrically conductive to oxygen ions. Because the oxygen content in the exhaust sample chamber is less than the oxygen concentration in the atmosphere, the oxygen content absorbed by the

FIGURE 16-28 The voltage signal produced by a wide-band oxygen sensor. Note that unlike gasoline engine O_2 sensors, the current flow continues to increase past the stoichiometric ratio.

FIGURE 16-29 A cross section of a wide-range planar oxygen sensor.

platinum coating on the ZrO_2 ceramic that contacts the exhaust and the coating that contacts the air will be slightly different (**FIGURE 16-30**).

This chemical difference in the sensor ceramic generates a voltage proportional to the oxygen content in the exhaust stream. The greater the difference in oxygen content, the higher the voltage. This voltage is produced because of the galvanic effect in which dissimilar metals in the presence of an electrolyte will produce electric current. Using the voltage produced across the two coatings, an amplifier circuit, called an oxygen pump cell circuit, will transfer excess electrons from the coating in the exhaust gas chamber to an electron-depleted electrode in the atmospheric reference chamber. The amount of current

FIGURE 16-30 Voltage is generated when the oxygen composition of the platinum coatings on ZrO_2 is different due to a change in the relative oxygen content of the coatings.

used to transfer these electrons is proportional to air–fuel ratio, and a circuit will precisely calculate air–fuel ratios based on the amount of current required to balance the voltage differential.

NOx Sensors

NOx sensors are used to evaluate the operation of selective catalyst reduction (SCR) systems. These sensors measure NOx from the engine and NOx from the tailpipe, and they should verify a dramatic drop in NOx emissions. NOx sensors are constructed and operate similarly to wide-range planar oxygen sensors using ZrO_2 ceramic substrate, except different concentrations of alloys are used in the NOx sensor's platinum sensor walls. Also, NOx sensors include a chamber that first removes excess oxygen, then separates NOx into nitrogen and oxygen, and then pumps the resulting oxygen through the chamber walls. The two-chamber shape and the multilayered platinum element enable these sensors to differentiate with high precision oxygen ions originating from nitric oxide (NO) from among the oxygen ions present in the exhaust gas.

The NOx sensor's ZrO_2 chamber, which is the size of a thumbnail, is heated to 1,200°F (700°C). It is housed in a metal can that has a hole for exhaust gas entrance. The chamber walls break apart the NO into nitrogen and oxygen components. The amount of oxygen produced at this stage is proportional to the amount of NO. ZrO_2 ceramic substrate will pump oxygen through the wall when a current is placed on both sides of the chamber wall. As oxygen is pumped from the first chamber, the amount of oxygen can be measured as it passes through the wall of the second chamber because it generates a voltage proportional to its concentration. Because the oxygen ions originated only from NOx, an accurate measure is derived for NOx in the exhaust gas. A module connected to the sensor conditions the electrical signal to represent a value for the amount of NOx sensed in the exhaust stream (FIGURE 16-31).

Ammonia Sensors

A NOx SCR system used on late-model diesel engines involves injecting urea, a colorless and odorless liquid, into the exhaust stream. Once exposed to exhaust heat, the urea quickly breaks down to form ammonia, which reacts with NOx and renders it into harmless nitrogen, water, and oxygen molecules. However, ammonia is a noxious substance and should not escape into the atmosphere. The potential for ammonia to be released to the atmosphere has led to the required use of an ammonia sensor for most engines produced since 2014. The **ammonia sensor** provides data to the ECM that is used to determine whether excess ammonia is detected. Constructed like a wide-range planar NOx or oxygen sensor, an ammonia sensor uses an aluminum oxide substrate rather than a ZrO_2 planar element to detect and generate a voltage for ammonia in a range from 0 to 100 ppm.

Soot Sensors

Another new sensor introduced in 2014 is a particulate sensor, which measures any soot present in the exhaust. This sensor is a type of variable capacitance sensor that uses soot to change the dielectric strength between two charged plates. Increasing amounts of soot or particulate matter will reduce the dielectric strength and the electric charge that the plates can store.

Mass Airflow Sensors

The mass airflow (MAF) sensor is a device that measures the weight of air entering the engine intake. Its unique design also reports data about air density and, to some extent, the vapor content.

MAF sensors are common on engines operating at stoichiometric air–fuel ratios. However, on the diesel engines operating with an excess air ratio, the MAF is used as part of

FIGURE 16-31 Operation of a NOx sensor. These sensors are also sensitive to any nitrogen in the exhaust stream and can detect ammonia gas as well.

the heavy-duty onboard diagnostics (HD-OBD) component monitor for the EGR. A variety of electrical signals originate from MAF sensors, but they all work using a hot-wire operating principle. Heated platinum wires or a thin film of silicon nitride embedded with several heated platinum wires are located in the intake air stream. A heating circuit maintains a fixed voltage drop across the wires, maintaining a constant resistance and temperature of the wires regardless of the airflow in the intake system. This means that if a voltage drop of 5 volts is maintained across the heated wire, more current needs to flow through the wire if it cools faster due to increased airflow. Similarly, if airflow drops, less current is needed to maintain the same voltage drop across the wire (**FIGURE 16-32**).

Circuits internal to the MAF measure the variation in current flow proportional to the cooling effect of air mass. Due to the large valve overlap characteristic of diesel engines, some intake air may be forced back out in pulses from the intake system. MAF sensors on some engines use a reverse airflow detection circuit. Because colder air is denser than warmer air, manufacturers will also use an air temperature sensor to provide additional data for calculations to compensate for the change in air mass (**FIGURE 16-33**).

Output Circuits

Output circuits, or output control devices, consist of display devices, serial data for network communication, and electromagnetic operator devices. The two basic types of operators are solenoids and relays. Injectors will use solenoids to meter fuel and adjust the timing of injection events.

Transistors inside the ECM are most often used to open or close circuits that control these operators. A small amount of current flowing from the microprocessor through the transistor base will control the output devices by supplying either a ground or battery current to complete a circuit (**FIGURE 16-34**).

Output drivers use field effect transistors (FETs) that are switched either on or off with very small voltages and produce little heat, which makes them ideal for output drivers.

FIGURE 16-32 Heated wires that change resistance as airflow across the sensor increases or decreases. Air mass is calculated based on how much electrical current is required to cancel the cooling effect of airflow across a heated wire.

FIGURE 16-33 A combination pressure and temperature sensor is used to calculate air mass entering an engine using a speed density algorithm. Note the two white signal wires.

► Sensors and Position Calculations

K16002

Engine control systems need to determine the correct cylinder and point in the combustion cycle for injection. In order to send an electrical signal to fire the injectors, the ECM needs to know two things:

1. *Crankshaft position.* The ECM must know the exact position of the crankshaft in reference to TDC—that is, the number of degrees the crankshaft has rotated since it turned past TDC.
2. *Cylinder identification.* This information is necessary to determine in which cylinder the injection event should take place, based on cylinder stroke position. Once the ECM can determine when the first cylinder has reached TDC compression stroke, it can use the engine firing order stored in memory to fire the remaining cylinders in the correct sequence. However, because the crankshaft rotates through 720 degrees of a four-stroke operating cycle, or two rotations of the crankshaft, cylinder stroke for any given cylinder can be determined only after the camshaft has passed through at least one revolution. To measure crankshaft position and identify cylinder stroke to begin a firing sequence, manufacturers have developed a number of strategies using either variable reluctance or Hall-effect sensors.

Single Engine Position Sensor

Teeth or raised lugs on a cam gear that turns at one-half engine speed can generate signals using a Hall-effect or variable reluctance sensor. A number of evenly spaced reluctor teeth, corresponding to the number of cylinders that an engine has, will produce a waveform or pattern that can be used to calculate the rotational velocity and engine position. This means that for every tooth that passes over the sensor, the ECM can calculate a specific number of degrees of crank or camshaft rotation has

FIGURE 16-34 Transistors in the ECM control output devices by providing either a ground or a battery positive current to complete a circuit.

occurred. Counting the signals produced by reluctor wheel teeth and measuring the time elapsed between signals generated by the sensor allows the ECM to precisely calculate engine rotation in fractions of degrees.

Evenly spaced reluctor ring teeth or lugs, however, will not identify the cylinder stroke position. To identify TDC of the first cylinder's compression stroke, the cam gear may use an additional tooth or lug to identify the stroke position of each cylinder. A seventh tooth or lug on the cam gear of a six-cylinder engine could correspond to TDC of the first cylinder's compression stroke. Alternatively, a manufacturer may remove a tooth from a reluctor wheel. The longer time between two teeth is detected by the ECM's analysis of the sensor's waveform and will identify cylinder stroke as, say, TDC of the first cylinder (**FIGURE 16-35**).

Variations of this basic strategy include using one or two narrower teeth or an odd arrangement of teeth that corresponds to a particular engine position for a given waveform. It should be noted that the additional or missing tooth strategy may require as many as three crankshaft revolutions before the ECM can determine what the cylinder stroke position is.

Using Two Sensors

A better strategy than using a single sensor on the camshaft is to use both camshaft and crankshaft position sensors. Using

FIGURE 16-35 The waveform produced by a camshaft gear with a missing tooth on the signal generator wheel.

two sensors yields the advantage of improved precision in calculating crankshaft position. Using only the camshaft sensor, error is introduced due to backlash between the crankshaft

FIGURE 16-36 Two sensors produce crankshaft and engine position data with little error when compared to a single sensor on the camshaft. The camshaft reluctor wheel of a Hall-effect sensor produced the top waveform. A variable reluctance sensor generated the crankshaft waveform.

and camshaft gears. Worn gears can result in a significant amount of gear train backlash, producing unacceptable error in reporting crankshaft position. Using the crank sensor, the ECM can determine exactly where the position of the piston is (**FIGURE 16-36**).

Cylinder Misfire and Contribution Detection

The crankshaft of a diesel engine will speed up and slow down with each power and compression stroke in the engine. The waveform that is generated from the engine position sensor(s) can determine the rotational velocity of the crank. A cylinder that is misfiring or producing little power in comparison to the other cylinders will turn more slowly, resulting in fewer teeth passing the position sensor per unit of time. Analyzing sensor waveforms using edge detection software algorithms, the ECM can determine how much power each cylinder is contributing to overall performance. Similarly, a loss of compression in a cylinder results in less crankshaft deceleration during an operating cycle. The ECM may change injection quantities to even out cylinder contribution based on data from the crankshaft and camshaft position sensors.

► Sensor Fault Detection Principles

KI6003, SI6001, SI6002

Technicians are often called upon to diagnose fault codes associated with sensors or sensor circuits. Understanding how sensor-related faults are detected and the diagnostic strategies used by an ECM will help you stay focused when performing pinpoint checks.

Sensors and Onboard Diagnostics

Electronic control systems have self-diagnostic capabilities to identify faults in circuits and sensors. Without the ability of an ECM to monitor circuit operation, diagnosing faults would become an extraordinarily difficult task, requiring the technician to manually perform voltage, resistance, and current measurements for every circuit, with the potential to produce a particular symptom of system malfunction. Waveforms from sensors producing varying frequencies, pulse width modulation, digital, or sine wave would also require a staggering amount of time and resources to analyze.

Because modern machines are required by emission legislation to monitor engine and other system operations for

faults that could produce excessive emissions, evaluating sensor operation is a critical function of the HD-OBD system. There are three major categories of fault codes identified by engine manufacturer diagnostics (EMD) and HD-OBD:

1. **Out of range faults.** These faults primarily check sensor voltages, and in a few cases, they also check current draw to determine whether the sensor or associated circuits are open or have shorts. Voltages should be within 85% of reference voltage. That means for most sensors operating with a 5 Vref, signal voltages should not fall below 0.5 volts or above 4.5 volts (**FIGURE 16-37**).
2. **Rationality, plausibility, or logical faults.** Manufacturers use different terms to describe the same fault detection strategy whereby the validity or accuracy of sensor data is evaluated by comparing sensor voltages with expected values. Most often, sensor data from several more sensors or measurement systems is compared with data from a particular sensor to see if the data makes sense (that is, that it's logical or rational). Another name given to these types of faults is in-range faults, because the sensor could produce signal voltages that are not above or below a fault threshold voltage, but the sensor may have failed and is supplying incorrect data.
3. **Functionality faults.** HD-OBD systems are required to evaluate the operation of at least 12 to 14 other major emission systems, such as the exhaust aftertreatment, boost pressure, and EGR. Simple or elaborate fault detection strategies are used to check whether a particular emission system is functioning correctly. The major system monitors, as they are called, depend on sensor data to function, but they do not specifically check the sensor except to analyze the influence that sensor data has on a system. For example, if a system could not enter closed-loop operation because the sensor data was out of range, irrational, or had some problem with its operation, such as an abnormal operating frequency or switching time or a defective waveform, the sensor would be identified as having a fault. NOx sensor faults are a common example in which the sensor is working properly but, due to some other incorrect system function, the sensor is producing higher NOx levels, so the sensor is identified as defective. In other words, it is a concurrent code, not actually

the fault the system has. In many cases, the NOx sensor is identified as being faulty, but although problems with a catalytic converter, EGR valve, or restricted air-intake systems will produce what appears to be an in-range fault, the problem actually lies outside the sensor.

Comprehensive Component Monitor

The comprehensive component monitor (CCM) is one of the system monitors required for OBD systems. It is a continuous monitor that constantly checks for malfunctions in any engine or emission-related electrical circuit or component providing input or output signals to an ECM. Electrical inputs and outputs are evaluated for circuit continuity and shorts by measuring voltage drops in a circuit. The monitor is also responsible for performing rationality checks of sensors. For example, if an oil pressure sensor indicated the engine had 40 psi (276 kPa) of oil pressure and the engine was stopped, the data would not make sense, and therefore a rationality fault would be stored. Another example would be that of a coolant temperature sensor that indicated the coolant was warm, say 140°F (60°C), but all other sensors such as oil, fuel, air inlet, and transmission temperatures were at -20°F (-29°C) and the engine had just started after cold soaking for 20 hours. Such a code could be triggered by plugging in a block heater, or it might indicate a defective sensor. Rationality codes need careful pinpoint diagnostic tests to determine whether a sensor is defective or some outside influence is affecting sensor data.

Outputs such as injector solenoids, relays, and dosing valves are evaluated by the CCM for opens and shorts by monitoring a feedback circuit from the FET, or “smart driver” associated with the output circuit. Smart FETs, as they are called, are FETs designed to supply data about the amount of amperage passing through the transistor gate (**FIGURE 16-38**).

These same gates can operate as virtual fuses that can disconnect power to the circuit if current flow is excessive. CCM codes use failure mode indicators (FMIs) developed by the International Society of Automotive Engineers (SAE) that indicate how an electrical circuit has failed (**TABLE 16-1**).

Out-of-range voltage codes that are the most common when sensors and circuits are open or shorted include FMI 3

FIGURE 16-37 Out-of-range voltage codes on sensors are produced when the signal voltage falls outside 85% of reference voltage. This means signal voltages below 0.5 and above 4.5 typically trigger out-of-range voltage codes.

FIGURE 16-38 Smart FETs can provide feedback to the ECM about amperage moving through the transistor gate.

TABLE 16-1 American Society of Automotive Engineers (SAE) J1939 Failure Mode Identifier (FMI)

FMI	SAE Text
0	Data valid but above normal operational range—most severe level
1	Data valid but below normal operational range—most severe level
2	Data erratic, intermittent, or incorrect
3	Voltage above normal or shorted to high source
4	Voltage below normal or shorted to low source

31	Condition exists

and 4. J1587 and J1939 SAE rationality codes are 0, 1, and 2. J1939 also adds FMI codes 15–18, 20, and 21 for rationality-related faults. Codes 8–10 are used to report problems with

waveforms from sensors or systems. Codes 5 and 6 are used by smart drivers that detect excessive or insufficient amperage in a circuit. Only FMI codes 11–14, 19, and 31 are not used by the CCM.

Circuit Monitoring—Voltage Drop Measurement

The way in which switch operation is monitored inside helps provide a foundation for other circuits to monitor sensors. Two basic types of switch inputs to the ECM are pull-up and pull-down switches. The terms “pull-up” and “pull-down” are often used to describe whether current through a circuit is supplied by the positive or negative current polarity. Pull-up means current is originating from a positive voltage source, and pull-down from a negative source. In the case of switches, pull-up switches supply a positive battery voltage input while pull-down supply a ground or negative voltage input (FIGURE 16-39).

Inside the ECM, a current-limiting resistor is connected in series with either of the switch types. This current-limiting resistor splits the voltage drop across the resistor and switch contacts. Voltage will drop across the current-limiting resistor when switch contacts are opened or closed. A high-impedance microcontroller capable of measuring voltage between an internal ECM ground and the resistor is connected in series with the current-limiting resistor, which enables a voltage reading. This means that voltage drop across the current-limiting resistor, whether it is a pull-up or pull-down switch, is measured by a voltmeter. Switch status (i.e., whether open or closed) is determined by measuring the voltage dropped across the current-limiting resistor.

Pull-Up Resistors

When two resistors are connected in series, the greatest voltage drop takes place across the resistor with the highest resistance. The second resistor will drop the remaining voltage in a circuit. This is predicted by Kirchhoff’s law, which states that the sum of the voltage drops in a circuit equals source voltage (FIGURE 16-40).

Because the microcontroller inside the ECM that measures voltage has very high resistance, it behaves like the largest of the resistors in a circuit. A pull-up resistor will have most voltage drop measured if the external circuit is open, because it places the microcontroller in series with the pull-up resistor. In this case, only a small amount of voltage is dropped by the pull-up resistor and the most voltage is dropped through the highly resistive microcontroller. For example, out of a +5-volt reference supply, the pull-up resistor may drop 0.1 volts and the much more resistive microcontroller will drop the rest, or 4.9 volts. When the switch is closed, the very low resistance across the contacts will cause the most current to flow through the switch contacts and the series connected pull-up resistor. Almost no current flows through the highly resistive microcontroller, because the microcontroller is connected in parallel and has much higher resistance than the pull-up resistor and switch have, which are connected in series.

FIGURE 16-39 Pull-up switches supply a positive voltage to the ECM, while pull-down switches supply negative or ground.

FIGURE 16-40 With two resistors connected in series, most voltage will drop across the resistor of higher value, which is predicted by Ohm's law (voltage drop = amperage $\times$ resistance).

Smart-Diagnosable Switches

Disconnected switches, shorted switch wiring, and resistive switch contacts cannot be diagnosed using open or closed diagnostic logic. To differentiate a disconnected switch from an open switch, resistors are placed in series or in parallel with the switch (**FIGURE 16-41**).

This enables the microcontroller to identify problems in the wiring between the switch and ECM for failures such as shorted to ground or open-circuited wiring. When properly connected

in a functioning circuit, the resistor that is incorporated into the switch in series will have a calibrated resistance sensed by the microcontroller and measured as a specific voltage drop. If a switch has a resistor connected in parallel across its contacts, opening the switch provides a specific voltage drop measured by the microcontroller. If the switch wiring is shorted to ground or to battery positive or is simply disconnected, programmed logic within the microcontroller will identify the voltage reading as different from the switch resistance when opened or closed and log the appropriate fault code (**FIGURE 16-42**).

Pull-up resistors can be connected in series with the switches to further enhance the diagnostic capabilities of the microcontroller. Clutch, brake light, or AC pressure switches often use these arrangements because of their critical functions.

► TECHNICIAN TIP

It is a very important and fundamental principle of electrical troubleshooting that when an ECM stores a diagnostic code, the code generally points to a problem somewhere in the circuit and not necessarily to the device connected to the circuit. If a code for a sensor is logged, further pinpoint testing using a diagnostic flowchart is required to properly diagnose the circuit.

Regulated Reference Voltage (V_{ref})

Regulated voltage supplied to sensor circuits (V_{ref}) is important for several reasons. First, a stable and precise voltage is

FIGURE 16-41 Placing resistors in series with opening and closing switches with different resistor values distinguishes switch status for each of these “smart switches.”

FIGURE 16-42 Resistors internal to the microcontroller are used to identify the different switches in a machine for proper control logic.

necessary for accurate voltage drop calculations used to determine the unknown resistance value of a sensor. Without the regulated voltage supply, changes in system voltage would produce sensor error. Current-limiting resistors are supplied a voltage lower than battery V_{ref} to prevent excessive current flow through the microcontroller circuit if wiring becomes shorted. V_{ref} values are typically 5 volts. (There are some exceptions: Caterpillar uses 8 volts on some control systems.) An internal ground called ZVR is just as important. All sensors using reference voltage return current through the control module and

not to chassis ground. Variations in voltage at chassis ground would produce error in voltage drop calculations, resulting in incorrect signal voltages. The internal ground is also filtered and “cleaned,” meaning it is free of electromagnetic interference.

► TECHNICIAN TIP

Just as V_{ref} to sensors and switch circuits is regulated to typically +5 volts, a regulated ground circuit is provided through control modules. All sensors using reference voltage need a regulated ground return circuit through the

control module and never to machine ground in order to prevent electrical interference and variations to voltage measurements. The control module in turn is connected to machine ground, which is the only way the electronic control system can function effectively.

Two-Wire Pull-Up Circuit Monitoring

To identify faults and measure signal voltage, thermistors are often connected to internal pull-up resistors. Thermistors are variable resistors that change resistance with temperature. These temperature-sensing devices are monitored for the following:

- resistance to validate normal signal voltage and detect out-of-range faults
- opens, either internal or in the circuit wiring
- shorts to power
- shorts to ground.

Like switches, the control module will measure voltage drop across an internal current-limiting pull-up resistor to calculate voltage drop across a thermistor. NTC thermistors increase resistance when they become colder and decrease resistance when they become warmer. Measuring temperature is performed by calculating the voltage drop across the thermistor connected in series with the pull-up resistor. As the resistance of the thermistor increases, less voltage is dropped across the pull-up resistor and more across the thermistor. The microcontroller will measure more voltage drop across the pull-up resistor when the thermistor becomes less resistive. Unwanted extra resistance in the circuit will produce a higher voltage drop across the sensor, generating colder temperatures. An open circuit (high resistance) will read the coldest temperature possible. Circuit-monitoring fault detection is typically designed to recognize sensor resistance values within approximately 85% of the voltage supplied from the pull-up resistor to be within normal range, and voltage readings outside of that range are recognized as abnormal (FIGURE 16-43).

FIGURE 16-43 Circuit monitoring of thermistors involves measuring the voltage drop after a pull-up resistor. Fault code reports out-of-range signals at approximately 85% of V_{ref} . This FMI 3 description is voltage high or shorted high.

FIGURE 16-44 A thermistor with an SAE fault code of FMI 3: voltage high, shorted high.

The normal signal range used to diagnose most sensor circuits covers the entire operating range of the sensor signal, and the circuit should always have some resistance, whether hot or cold. A disconnected sensor will have infinite resistance, and no voltage is dropped across the thermistor. In these circumstances, the voltage reading by the circuit's microcontroller will see maximum voltage between its internal ground and the current-limiting resistor. An open sensor or disconnected open wiring will produce an SAE fault code description of "out-of-range high or shorted high" (FMI 3) (FIGURE 16-44).

The manufacturer and SAE FMI code descriptions point to the higher voltage sensed by the microcontroller because no voltage is dropped by the disconnected or open thermistor circuit and all voltage is now dropped by the microcontroller. Note that the sensor signal wire that is shorted to positive battery voltage or another +5-volt supply will generate an identical fault code as an open-circuited signal wire (FIGURE 16-45).

The logic used by the microcontroller that senses no or little voltage drop across the pull-up resistor could be caused by a positive voltage supply shorted to the signal wire. The ZVR could also be open and produce the same voltage readings by the microcontroller. Both conditions require appropriate pinpoint testing to isolate the fault.

FIGURE 16-45 A thermistor with an SAE fault code of FMI 3: Shorted high, voltage high.

If a thermistor signal wire is rubbed through and making contact to machine ground, more current will flow through the signal circuit and the fault code description typically includes the following:

- out-of-range low or shorted low (FMI 4)
- signal wire shorted to sensor return or battery negative (manufacturer code)
- signal source shorted to ground (manufacturer code).

Excessive current flow across the pull-up resistor connected in series with the grounded circuit means low or no voltage is measured between the pull-up resistor and the signal wire. Because most current will flow through the short to ground, little current will flow through the microcontroller, and the voltage drop will be less than 0.5 volts. This explains why the code description given is out-of-range low or shorted low (FMI 4). Diagnostic logic programmed into the microcontroller points to a short to ground, causing excessive voltage drop across the current-limiting resistor of more than 85% of the voltage supplied to the resistor (**TABLE 16-2**).

Manufacturers can go beyond SAE minimum standards for reporting faults using J1939 protocols and add additional fault code descriptions using their own coding system. In the case of the disconnected thermistor, an enhanced code could carry a code description such as “signal wire shorted to sensor supply,” “short to battery volt,” “signal source shorted to voltage source,” “open return,” or “signal circuit.”

► **TECHNICIAN TIP**

Pressure, temperature position, and other sensors can share a +5Vref or ZVR wire. Return is the equivalent to machine ground through the control module, which is free of electromagnetic interference and is regulated to provide the cleanest signal path. Problems in the reference voltage or signal return path can cause unusual problems and multiple fault codes from all the sensors. “Shorted high or low” and “voltage high or low” are typical fault code descriptions produced if sensors share common Vref and ZVR pathways. This happens because the voltage supplied to the sensors has changed. Less than +5 volts or the absence of a ZVR distorts the ECM’s ability to properly sense correct signal voltages. If the return is connected to machine ground, voltage fluctuations and electromagnetic interference can sometimes distort electrical signals and measurement of voltage drops across the sensor circuits. A single defective sensor may have an internal short circuit to ground and +5 volts,

which can interfere with the operation of all sensors. Disconnecting a defective sensor can sometimes cause the multiple fault code to disappear. The use of an LED diode installed in series with the ZVR circuit at each sensor can detect a malfunctioning circuit or device because the polarity-sensitive LED will light both directions when connected to the defective sensor.

► **TECHNICIAN TIP**

Just because a control module does not log a fault code does not mean that no problems exist in the electronic control system. Because the normal signal range (within 85%) used to diagnose most sensor circuits spans the entire operating range of the sensor; it is possible for the sensor to produce a signal that does not measure the actual operating condition and therefore will not be identified with a fault code. A good strategy to identify problems is to monitor signal voltage using a scanner or software data list while comparing observed values with expected values reported in a shop manual.

► **TECHNICIAN TIP**

Quick-testing to determine whether a fault code is generated by defective wiring, pin connectors, or a sensor can be performed using jumper wires. While monitoring sensor signal voltage using an electronic service tool, the signal voltage values should change when either disconnecting the sensor or jumping sensor signal wires to ZVR or +5 Vref. If no change is observed when momentarily grounding the signal wire or supplying the signal wire with +5 Vref, the wiring or pin connections in the circuit are suspect. Some manufacturers recommend using a calibrated resistor in series with the jumper wire when performing these tests, in order to prevent damage to sensitive control modules.

Three-Wire Sensor Circuit Monitoring

Three-wire circuits, whether digital or analog, passive or active, use a reference voltage, signal, and ZVR wire, also referred to as ground return by some manufacturers. Voltage out-of-range faults (FMI 3 and 4) are detected when the signal voltage from a sensor typically exceeds the 0.5–4.5 volts out-of-range fault threshold (**TABLE 16-3**).

TABLE 16-2 Out-of-Range Voltage Fault Code Descriptions Using a Pull-Up Resistor (i.e., two-wire NTC thermistor)

Condition	Observation	Code Description
Sensor disconnected	Signal voltage higher than 4.5 volts	FMI 3: Out of range high, shorted high
Signal wire shorted to positive voltage (12v battery or +5 volts reference)	Signal voltage higher than 4.5 volts	FMI 3: Out of range high, shorted high
Sensor open	Signal voltage higher than 4.5 volts	FMI 3: Out of range high, shorted high
Sensor signal wire shorted to ground	Signal voltage lower than 0.5 volts	FMI 4: Out of range low, shorted low
Sensor internally shorted to ground or ZVR	Signal voltage lower than 0.5 volts	FMI 4: Out of range low, shorted low

TABLE 16-3 Out-of-Range Voltage Fault Code Descriptions Using a Pull-Down Resistor (i.e., three-wire potentiometer)

Condition	Observation	Code Description
Sensor disconnected	Signal voltage lower than 0.5 volts	FMI 4: Out of range low, shorted low
Signal wire shorted to positive voltage (12v battery or +5 Vref)	Signal voltage higher than 4.5 volts	FMI 3: Out of range high, shorted high
Sensor open	Signal voltage lower than 0.5 volts	FMI 4: Out of range low, shorted low
Sensor signal wire shorted to ground	Signal voltage lower than 0.5 volts	FMI 4: Out of range low, shorted low
Sensor internally shorted to ground or ZVR	Signal voltage lower than 0.5 volts	FMI 4: Out of range low, shorted low

The majority of three-wire sensors typically measure signal voltage between the positive voltage on the signal wire and the ZVR wire across a pull-down resistor (**FIGURE 16-46**).

However, some active three-wire sensors such as Hall-effect sensors and several manufacturers of pressure sensors supply variable resistance ground path for a +5 Vref from the ECM through the sensor's ZVR (**FIGURE 16-47**).

In this case, measuring signal voltage with three-wire sensors involves using a pull-up or pull-down resistor located in the ECM. In the case of a circuit using a pull-down resistor, a voltage-measuring microcontroller connected in parallel across

FIGURE 16-46 A low-bias sensor using a pull-down resistor. The sensor voltage is measured across the pull-down resistor.

the pull-down resistor measures voltage drop across the resistor between the positive signal wire and the negative ZVR. Because there is only one pull-down resistor, all the voltage supplied by the signal wire will be dropped across the pull-down resistor. This means that a defective active type sensor will have a fault code of FMI 4 for low voltage or shorted low if the +5 Vref and ZVR circuits are open (**FIGURE 16-48**).

Because no current is supplied to the active sensor with either an open Vref or ZVR, internal sensor circuits cannot operate and supply a varying signal voltage. Voltage in this case would be 0, which is below the 0.5-volt fault threshold for low

FIGURE 16-47 This Hall-effect sensor supplies a ground path through the sensor for signal voltage. Disconnecting the sensor produces an out-of-range +5 volts signal, which makes it a high-bias three-wire active sensor. Grounding the signal wire produces a 0-volt signal.

FIGURE 16-48 A signal wire of a three-wire active sensor shorted to ground produces a fault code of FMI 4: shorted low, voltage low.

voltage. A short to ground signal wire will produce an identical shorted-low, voltage-low FMI fault code.

If the sensor supplies a ground path for a signal circuit from the ECM containing a pull-up resistor carrying +5 volts, a disconnected sensor will produce a voltage high, shorted high FMI fault code. In this instance, the active sensor cannot work and provide an electronically variable resistance to ZVR for the current supplied through the pull-up resistor. This means the microcontroller will see +5 volts on the signal wire and produce a fault code of FMI 3: voltage high, shorted high—as illustrated in Figure 16-47.

High- and Low-Bias Sensors

Whenever a sensor is disconnected or open, the out-of-range voltage code will be either out-of-range high or out-of-range low. If the arrangement of the pull-up resistor causes signal voltage to go high when disconnected, it is considered a high-bias resistor. That is, it has a bias or tendency to produce a fault code of out-of-range high, voltage high, or FMI 3. If the tendency for a sensor circuit is to produce a voltage-low code when disconnected, it is considered a low-bias sensor. Generally, high-bias sensors use a pull-up resistor and low-bias sensors monitor signal voltage with a pull-down resistor.

Circuits using pull-up and pull-down resistors have the added advantage of limiting excessive current flow to a sensor to protect the wiring, sensor, or control module if a short to ground or battery positive takes place. Excessive current flow from an internally shorted sensor or Vref wires would be lowered by the resistors when a fault condition exists. By limiting excessive current flow during shorted conditions in sensor circuits, Vref and ZVR circuits are protected as well.

More comprehensive circuit monitoring also takes place between the Vref and ZVR in some but not all control systems. Open, shorted to ground, or shorted to voltage source or resistive circuit pathways result in fault codes for these circuits.

Because ZVR is common to the sensors, problems with the reference voltage to a specific sensor circuit may be all that is detected.

► TECHNICIAN TIP

After performing a repair to an electronic control system, the repair should be validated before returning a machine to service to confirm the fault code does not reappear. In HD-OBD systems, repair validation requires operating the circuit or device under the enabling conditions for a major system monitor to run and obtain a system readiness code. Make sure the conditions to operate the device or run the monitor are met during the testing procedure. These procedures are outlined in the service manual. Double-check that no codes are pending or waiting to illuminate a malfunction indicator lamp (MIL). Occasionally, diagnostic codes can be set during routine service procedures or by problems outside the electronic control system. Always clear codes and confirm that they reappear prior to circuit troubleshooting. Comprehensive monitor codes on HD-OBD equipment often require only cycling the ignition switch on and off after a repair is completed to extinguish the MIL light.

► TECHNICIAN TIP

Tools required for fault isolation pinpoint testing include a digital volt-ohmmeter (DVOM) and some test leads or jumper wires. Proper break-out harness or pin connectors are needed to access the various connectors and components to be tested. Using improper tools can result in damage to pins and connectors and faulty meter readings, causing misleading diagnoses and producing even more diagnostic codes.

► TECHNICIAN TIP

If an intermittent fault is suspected, a physical check of the suspect circuit can be performed by flexing connectors and harnesses at likely failure points while monitoring the circuit with a multimeter or oscilloscope. Graphing meters with glitch testing capabilities can identify and record the circuit fault in microseconds. If the problem is related to temperature, vibration, or moisture, the circuit or control module can be heated, lightly tapped, or even sprayed with water to simulate the failure conditions. Some testing software features pull test capabilities, which can provide an audible alert when brief interruption in circuit voltages takes place when pulling or bending wiring harnesses.

Low- and High-Side Driver Faults

A large variety of electrical devices, such as relays, motors, and injectors, depend on current supplied from a control module to operate. When supplying a negative polarity or ground to a device, current is switched through a transistor called a low-side driver. Similarly, switching transistors supplying positive DC voltage are referred to as high-side drivers. Two techniques are used to detect opens, shorts, high resistance, and excessive current draw in these circuits. Current-limiting resistors used to measure voltage drop in the output circuit, much like in sensor circuits, are used to evaluate circuit performance. Another method involves direct measurement of output current using smart FETs (FIGURE 16-49).

FIGURE 16-49 **A.** The rail pressure is controlled by the electronic fuel control valve. **B.** Amperage to the valve is measured by feedback from FETs inside the ECM.

In these circuits, the drain-to-source current flows are measured through a special feedback circuit to the microcontroller. Time on and amperage are used to set fault codes. FMIs 5 and 6 are produced when amperage exceeds out-of-range thresholds. FMI 5—current below normal or open—is produced if little or no amperage flows through the output circuit. FMI 6—current above normal or grounded—indicates a short to grounded circuit with high current flow (**FIGURE 16-50**).

For example, an injector that is supplied 2 amps at 70 volts using a high-side driver would be considered open if no current flowed or considered shorted to ground if amperage exceeded, say, 5 amps.

► TECHNICIAN TIP

To validate a repair, start the engine and let it idle for one minute. The ECM will turn off the red MIL light whenever the diagnostic monitor has run. If it is a CCM evaluating electrical circuits, the light will switch off immediately when this diagnostic monitor runs and passes. For other faults, the ECM will turn off the MIL after three consecutive ignition cycles in which the diagnostic runs and passes.

FIGURE 16-50 Circuit monitoring of FET output drivers for self-diagnostic fault monitoring.

Maintenance of Sensors

The onboard diagnostic system capabilities are limited and can only narrow a fault to a circuit or system. After that, the technician must identify what the nature of the problem is that produced the diagnostic fault code. Servicing of sensor faults involves performing pinpoint electrical tests and making other observations to identify precisely where and what caused the fault. This stage of diagnostic testing is called off-board diagnostics.

Diagnostic Testing of Pressure Sensors

Diagnostic tests of pressure sensors are similar to other strategies for evaluating three-wire sensors. Onboard diagnostic systems will identify problems in the circuits. Scan tools can then measure real-time data to observe abnormal but in-range functional problems and retrieve fault codes associated with the circuits (**TABLE 16-4**).

Pinpoint tests using break-out harnesses are performed on live circuits too. Resistance tests are used to identify shorted or open wires in harnesses to these sensors. However, because these are active sensors with sensitive electronic circuits, it is not possible to perform resistance tests on the sensors themselves.

TABLE 16-4 Fault Code Descriptions for a Two- or Three-Wire Sensor

Condition	Observation	Code Description
In-range voltage but signal not valid	No rationality or plausibility when data compared with normal system behavior or other sensor inputs	In-range fault

SAFETY TIP

Never use a 12-volt jumper wire connected to battery positive to quickly check sensor harnesses. The ECM can easily be damaged by this method.

Diagnostic Testing of Thermistors

The range of resistance values of a thermistor varies by manufacturer and what temperature range the sensor measures. The change in resistance is not linear or directly proportional to temperature, either (TABLE 16-5).

At the low and high ends of a temperature range, small changes in temperature produce large changes in resistance, while changes in midrange temperature values produce smaller changes to sensor resistance. Several temperature and resistance values are supplied by the manufacturer to properly evaluate a thermistor when testing the use of an ohmmeter.

Diagnostic Testing of Variable Reluctance Sensors

Variable reluctance sensors are two-wire passive sensors. The coil of wire surrounding a magnet should be tested for continuity and should have its resistance measured. Resistance is high because there are hundreds of wire winding turns and the wire diameter is very small. The output of the sensor can be measured with an AC voltmeter. As the reluctor speed increases, the voltage produced by the sensor will rise proportionately.

A broken magnet will cause a low voltage reading. Likewise, an improper air gap between the sensor and reluctor will cause sensor output failure. Iron filings at the magnet of the sensor will also cause an inadequate change in sensor reluctance, generating insufficient voltage. Simply removing, cleaning, and reinstalling the sensor can sometimes correct inadequate or erratic sensor signals.

Variable reluctance sensor operation can often be evaluated from a scan tool or waveform graphing meter. For example, if an engine speed sensor is defective, engine speed data cannot be

TABLE 16-5 The Inverse and Nonlinear Relationship Between Temperature and Resistance of a Thermistor

Temperature		Resistance
°Celsius	°Fahrenheit	Ohms
100	210	185
70	160	450
38	100	1,600
20	70	3,400
-4	40	7,500
-7	20	13,500
-18	0	250,000
-40	-40	100,700

observed from a scanner. Graphing meters can compare known good sensor waveforms with observed waveforms to detect sensor faults.

Diagnostic Testing of Hall-Effect Sensors

Diagnostic testing of Hall-effect sensors will follow similar diagnostic strategies for any other three-wire active sensor (FIGURE 16-51).

Out-of-range faults on the sensor can be pinpoint tested with a voltmeter by first verifying that +5 Vref and ZVR are available to the sensor (FIGURE 16-52).

After disconnecting the sensor and harness plug, quickly check to differentiate between a defective sensor and defective wiring harness by shorting the +5 Vref to the signal return circuit. While monitoring sensor voltage using software or a scanner connected to the diagnostic data link connector, the

FIGURE 16-51 Signal voltage when pinpoint testing is always measured between the ground return and signal wire for all sensors.

FIGURE 16-52 Confirming the availability of +5Vref is an important step in pinpoint diagnostics to isolate a fault; 5 volts can be measured from either chassis ground or sensor ground return. To confirm both signals are accurate, measure ground return and +5Vref.

signal voltage will show 5 volts or an “on” state. If there is no change in the voltage, the wiring harness or connector plugs are likely defective. Shorts of any of the circuit wires to ground, to battery voltage, or to one another are checked using either an ohmmeter when the machine battery is disconnected or measuring voltages in the sensor harness when the circuit is live.

Another important check of Hall-effect sensors is made using a graphing meter. Sometimes the circuit board within the sensor can fail and produce a waveform unrecognizable to the ECM, such as when the edges of a normally square waveform are not sharp and well defined. This often happens during a hot soak period, and the machine will not start until the engine cools. A graphing meter allows examination of the waveform for comparison between known good waveforms.

Diagnostics of Mass Airflow Sensors

MAF sensors produce waveforms or data that can be observed by using a graphing meter. Sensor operation can also be monitored using a scanner, OEM software, or a multimeter with a break-out harness. Diagnostics of MAF sensors will follow those of any three-wire active sensor. It is also important to remember that turbulence and airflow velocity variations can give false signals. For example, dirty heater wires, hot film, or film wires can cause incorrect readings. Screens placed inside the sensor to reduce turbulence can catch debris. These parts will require cleaning or replacement to restore proper operation. If the heater wire is intermittently breaking open, tapping the sensor to disconnect the wire will reveal the glitch if the sensor output is observed on a graphing meter or scanner.

Wrap-Up

Ready for Review

- ▶ Devices that convert one form of energy into another are called transducers. Sensors are a type of transducer because they convert physical conditions or states into electrical data. Pressure, temperature, angle, speed, and mass are just a few of the physical variables about which sensors supply electrical data to processors.
- ▶ A sensor is considered active or passive depending on whether it uses power supplied by the ECM to operate.
- ▶ Reference voltage refers to a precisely regulated voltage supplied by the ECM to sensors. It is significant to processor operation because the value of the variable resistor can be calculated by measuring voltage drop across the resistor with a known input voltage.
- ▶ Other classifications of sensors include resistive sensors, voltage generators, switch sensors, variable capacitance pressure sensors, and piezo-pressure and piezoresistive sensors.
- ▶ Switches are the simplest sensors of all because they have no resistance in the closed position and infinite resistance in the open position. Switches are categorized as sensors whenever they provide information to an electronic control system.
- ▶ The simplest digital signal is a single pole, single throw (SPST) switch. It is found in either an open or a closed state.
- ▶ When a switch is connected between the ECM and a battery positive, it is known as a pull-up circuit. A pull-down circuit is constructed when current to the switch is connected between the ECM and a negative ground current potential.
- ▶ Resistive sensors belong to the class of sensors that condition or change a voltage signal applied to the sensor. Many types of resistive sensors exist.
- ▶ A thermistor is a temperature-sensitive variable resistor commonly used to measure coolant, oil, fuel, or air temperature. The most common type of thermistor is an NTC thermistor.
- ▶ Rheostats are two-wire variable resistance sensors. They are not commonly used as input devices to an ECM, but instead are used for sending units such as fuel level, oil pressure, and some temperature gauges.
- ▶ Three-wire sensors, regardless of how they appear or what function they perform, have a common wiring configuration. The first wire provides reference voltage to the sensor. The second wire provides a negative ground signal to the ECM. The third wire is a signal return from the sensor. The advantage of using three-wire sensors is that they provide comprehensive diagnostic information about the sensor and its circuit operation.
- ▶ Potentiometers are similar to rheostats in that they vary signal voltage depending on the position of a sliding contact or wiper moving across a resistive material. However, they are three-wire sensors with the signal wire connected to the internal wiper. Potentiometers supply analog data to processing circuits.
- ▶ Pressure measurements such as intake manifold boost, barometric pressure, and oil and fuel pressure use two types of sensor technology: One is a variable capacitance sensor and the other uses strain gauge resistive sensors. These are both active sensors that produce analog output signals.
- ▶ Strain gauge measurements record small changes in the resistance of tiny wires caused by the stretching or contraction of the wires.
- ▶ Piezoresistive sensors rely on the ability of certain mineral crystals to produce voltage or change resistance when compressed. Rather than using a strain gauge resistor wire construction, these sensors use a

piezoresistive crystal arranged with a Wheatstone bridge to measure the change in resistance of the piezo crystal. The advantage of these sensors is their ability to measure very high pressures.

- ▶ A variable capacitance sensor is an active pressure sensor used to measure both dynamic and static pressure.
- ▶ Voltage generators are passive and produce an analog signal of varying voltage or AC frequency.
- ▶ Variable reluctance sensors are used to measure rotational speed. Wheel speed, machine speed, engine speed, and camshaft and crankshaft position sensors are common applications of these sensors.
- ▶ A material's ability to conduct or resist magnetic lines of force is known as reluctance. Variable reluctance sensors use changing sensor reluctance to induce current flow by changing magnetic-field strengths inside the sensor.
- ▶ Like variable reluctance sensors, Hall-effect sensors are commonly used to measure rotational speed of a shaft. Though they are more complex and expensive to manufacture than variable reluctance sensors are, they produce a digital signal square waveform and have strong signal strength at low shaft rotational speeds.
- ▶ Oxygen sensors are used to adjust EGR flow on diesels and exhaust oxygen content for exhaust after treatment devices.
- ▶ NOx sensors are constructed and operate similarly to wide-range planar oxygen sensors, except that different concentrations of alloys are used in the sensor walls.
- ▶ Constructed like a wide-range planar NOx or oxygen sensor, an ammonia sensor uses an aluminum oxide substrate rather than a ZrO_2 element to detect and generate a voltage for ammonia in a range from 0 to 100 ppm.
- ▶ The mass MAF sensor measures the weight of air entering the engine intake. Its unique design also reports data about air density and, to some extent, the vapor content.
- ▶ MAF sensors are common on engines operating at stoichiometric air-fuel ratios. However, on diesel engines operating with an excess air ratio, the MAF is used as part of the HD-OBD component monitor for the EGR. A variety of electrical signals originate from MAF sensors, but they all work using a hot-wire operating principle.
- ▶ Output control devices consist of display devices, serial data for network communication, and operators—electromagnetic devices that transform electrical current into movement. Two basic types of operators are solenoids and relays.
- ▶ ECMs need to determine the correct cylinder and point in the combustion cycle for injection. To send an electrical signal for firing the injectors, the ECM needs to know two things: crankshaft position and the stroke that a cylinder is on.
- ▶ Using teeth or raised lugs on a cam gear that turns at one-half engine speed can generate engine position data using a Hall-effect or variable reluctance sensor.
- ▶ A better strategy than using a single sensor on the camshaft is to use both a camshaft and crankshaft position sensor. Using two sensors yields the advantage of improved precision in calculating crankshaft position.
- ▶ The crankshaft of a diesel engine will speed up and slow down with each power and compression stroke in the engine. The waveform generated from the engine position sensor(s) can determine the rotational velocity of the crank. Analyzing sensor waveforms using edge detection software algorithms, the ECM can determine how much power each cylinder is contributing to overall performance.
- ▶ A thermistor's resistance value varies by manufacturer and the substance being measured.
- ▶ Variable reluctance sensors are two-wire passive sensors. The output of the sensor can be measured using an AC voltmeter. As the reluctor speed increases, the voltage produced by the sensor will rise proportionately.
- ▶ Hall-effect sensors can be tested and diagnosed in a similar way to any three-wire active sensor.
- ▶ MAF sensors produce waveforms that can be observed by using a graphing meter. Sensor operation can also be monitored by using a scanner or a multimeter. Diagnostics of MAF sensors follow those of any three-wire active sensor.

Key Terms

active sensor A sensor that uses a current supplied by the ECM to operate.

ammonia sensor A sensor used in selective catalyst reduction (SCR), which provides data to the ECM that is used to determine whether ammonia values are out of anticipated range.

Hall-effect sensor A sensor commonly used to measure the rotational speed of a shaft; they have the advantage of producing a digital signal square waveform and have strong signal strength at low shaft rotational speeds.

idle validation switch (IVS) A circuit used for safety reasons that is used to verify throttle position.

NOx sensor A sensor that detects oxygen ions originating from nitric oxide (NOx) from among the other oxygen ions present in the exhaust gas.

passive sensor A sensor that does not use a current supplied by the ECM to operate.

piezoresistive sensor A sensor that uses a piezoresistive crystal arranged with a Wheatstone bridge to measure the change in resistance of the piezo crystal; these sensors are adapted to measuring vibration and dynamic or continuous pressure changes.

potentiometer A variable resistor with three connections: one at each end of a resistive path, and a third sliding contact that moves along the resistive pathway.

pull-down switch A switch connected between the ECM and a negative ground current potential.

pull-up switch A switch connected between the ECM and a battery positive.

reference voltage (Vref) A precisely regulated voltage supplied by the ECM to sensors; the value is typically 5 VDC, but some manufacturers use 8 or 12 volts.

rheostat A variable resistor constructed of a fixed input terminal and a variable output terminal, which vary current flow by passing current through a long resistive tightly coiled wire.

thermistor A temperature-sensitive variable resistor commonly used to measure coolant, oil, fuel, and air temperatures.

variable capacitance pressure sensor An active sensor that measures both dynamic and static pressure.

variable reluctance sensor A sensor used to measure rotational speed, including wheel speed, machine speed, engine speed, and camshaft and crankshaft position.

wide-range planar sensor A type of sensor technology that uses a current pump to calculate relative concentrations of oxygen, nitric oxide, and ammonia in exhaust gases.

Review Questions

- Which type of input sensor is used by the engine management system and uses power supplied by the machine's ECM?
 - Active
 - Passive
 - Inactive
 - Delta
- The use of a reference voltage is important in engine computer processor operation, because the value of the variable resistor can be calculated by measuring which of these values when another resistor with a known voltage input is connected in series with the variable resistor?
 - Increase in voltage
 - Voltage drop
 - Amperage drop
 - Decrease in resistance
- To make sure that an engine fuel system drivability malfunction is identified and repaired correctly, always refer to _____.
 - aftermarket service manuals
 - diagnostic trouble code (DTC) diagnoses
 - aftermarket training manuals
 - OEM owners' manuals
- Which of these is LEAST LIKELY to be used as a potentiometer in a diesel engine management system?
 - Throttle position sensor (TPS)
 - Accelerator pedal position (APP) sensor
 - Accelerator position sensor (APS)
 - Mass air flow (MAF) sensor
- Which of these devices measures small changes in the resistance of tiny wires caused by stretching or contraction?
 - Strain gauge
 - Wire gauge
 - Potentiometer
 - Thermometer
- _____ voltage is a precisely regulated voltage supplied by the ECM to sensors.
 - Supply
 - Reference
 - System
 - Control
- A _____ switch is connected between the ECM and a negative ground current potential.
 - pull-down
 - pull-up
 - resistive
 - conductive
- A two-wire sensor that changes resistance in proportion to temperature is called a _____.
 - variable resistor
 - thermistor
 - capacitor
 - transistor
- Consider an active-type pressure sensor that uses a pull-down resistor to identify signal faults. What fault code will likely be reported if the Vref wire is broken?
 - Voltage high or shorted high
 - Voltage low or shorted low
 - Missing Vref
 - Voltage high shorted low
- Which of these sensor designs has the advantage of producing a digital signal square waveform and has strong signal strength at low shaft rotational speeds?
 - Variable reluctance
 - Voltage generating
 - Variable capacitance
 - Hall effect

ASE Technician A/Technician B Style Questions

- Technician A says that passive sensors are not used in today's machine management systems. Technician B says that active sensors use current supplied by the ECM to operate. Who is correct?
 - Technician A
 - Technician B
 - Both Technician A and Technician B
 - Neither Technician A nor Technician B
- Two technicians are discussing engine management input sensors. Technician A says that switches are the simplest sensors of all because they have no resistance in the closed position and infinite resistance in the open position. Technician B says that a zero-volt signal would present as a closed switch, while 12 volts would present as an open switch. Who is correct?
 - Technician A
 - Technician B
 - Both Technician A and Technician B
 - Neither Technician A nor Technician B
- Technician A says that a knock sensor measuring abnormal combustion signals is a common application of piezoresis-

tive sensors. Technician B says that silicon-based piezoresistive sensors are very sensitive to slight pressure changes. Who is correct?

- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
4. Technician A says that a defective mass airflow sensor can be diagnosed by using a graphing meter and inspecting the waveform that it produces. Technician B says that only the ECM can identify a faulty sensor. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says that if a problem is related to temperature, vibration, or moisture, the circuit or control module can be heated, lightly tapped, or even sprayed with water to simulate the failure conditions. Technician A says that a graphing meter with glitch testing capabilities can identify and record a circuit fault in microseconds. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
6. Technician A says that switches are categorized as sensors whenever they provide information to an electronic control system. Technician B says that switch data may indicate a physical value such as open or closed, up or down, or high or low, or it may indicate on and off. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
7. Technician A says that disconnecting a high-bias sensor will likely produce the fault code description “voltage high

or shorted high.” Technician B says that the fault code most likely reported by a disconnected high-bias sensor is “voltage low or shorted low.” Who is correct?

- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says that wide-band oxygen sensors produce a voltage proportional to a specific exhaust gas oxygen level. Technician B says that oxygen sensors are used to measure air–fuel ratio in order to calibrate EGR flow rates and air–fuel ratios for exhaust aftertreatment devices. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
9. Two technicians are discussing variable reluctance sensors. Technician A says that a broken magnet in the sensor will cause a low voltage reading. Technician B says that excessive air gap between the sensor and reluctor will cause sensor output failure. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
10. Technician A says that *out-of-range faults* check sensor voltages and, in a few cases, current draw to determine whether the sensor or associated circuits are open or have shorts. Technician B says that *rationality faults* use a detection strategy whereby the validity or accuracy of sensor data is evaluated by comparing sensor voltages with expected values. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

CHAPTER 17

Electrical Instrumentation and Alarm Systems

Knowledge Objectives

After reading this chapter, you will be able to:

- **K17001** Identify and describe the construction and operation of warning devices and gauge systems.
- **K17002** Describe the operation of capacitance and resistive touch driver information screens.
- **K17003** Describe procedures to inspect, test, and adjust gauge sending units and circuits.

Skills Objectives

There are no skills objectives for this chapter.

► Introduction

Instrument gauges, warning lamps, and operator information centers enable the operator to monitor the machine's operating condition, the status of equipment, and safety systems. The types of displays, warning lights, and gauges differ widely among machines and manufacturers but can be categorized according to common gauge groups, sensing, and input systems. For example, monitoring engine operation involves measuring the pressure and temperature of parameters of the lubrication, cooling, and air induction system. Charging voltage and amperage of the electrical system, fuel level, air pressure, engine, and machine speed are other common gauge systems. Warning lights for systems ranging from torque converter temperature, hydraulic oil filter bypass, low fuel, low air pressure, glow plug, parking brakes, etc. are used in situations where limited but simplified information is useful. Newer digital instrumentation has superior accuracy plus built-in self-diagnostic capabilities, offering the operator confidence that gauges and warning systems are operational. Operator display and input systems connected to the machine network provide informational capabilities far beyond previous instrumentation design.

► Warning Lights and Gauges

K17001

Warning Lights

Warning lights provide easily understood information to alert the equipment operator to potentially dangerous operating conditions (FIGURE 17-1).

Low air pressure, park brake on, low diesel exhaust fluid, powertrain oil temperature, etc. are activated a number of ways:

- mechanical ground switches
- electronic switches
- voltage drop circuits.

The charging system indicator light is an example of a light operated through voltage drop (FIGURE 17-2).

FIGURE 17-1 Warning lights.

After the engine starts and the alternator begins charging, battery voltage and charging system voltage are applied to both terminals of a bulb. If battery voltage is equal to or becomes higher than the charging system voltage, the voltage differential will cause the light to illuminate.

Mechanical ground switches are used to indicate low fluid levels, low-pressure warning systems, or differential engagement locks (FIGURE 17-3).

Normally closed pressure switches opened with mechanical, air, or oil pressure provide a path to ground to illuminate a bulb (FIGURE 17-4).

Electronic switches found in electronic control modules are the most common way warning lights are illuminated in today's machines. If a condition is sensed to which the operator needs to be alerted, the module has control logic to supply a ground or battery voltage to the light.

Prove-Out Sequence

In order to validate the correct operation of a warning light, the instrument cluster is designed to illuminate a bulb for several

You Are the Mobile Heavy Equipment Technician

A late-model machine has arrived at your shop with several complaints related to the electrical system. One complaint is that the check engine light is continuously illuminated. Another is that the instrument gauges go to zero and sweep from zero to full scale and then back again to a correct reading while operating. Other times the instrument gauge cluster does not move at all when the machine is started and running. In addition to requesting that the electrical problems be corrected, the operator expresses concern about running out of fuel if the gauges are not reading accurately. Having time-sensitive construction deadlines, an incorrect fuel reading for a fuel tank that is empty would be financially disastrous to the company.

As you proceed to diagnose the problem, you discover that lightly pulling on the wiring harness connected to the gauge cluster duplicates the complaint about the gauges sweeping from zero to full scale and back again to a correct reading again. Consider the following to predict what you think the technician will write on the work order:

1. Explain why the gauges complete a full-scale sweep when electrical power is interrupted.
2. What is potentially the simplest procedure the technician could use to identify the problem illuminating the check engine light?
3. Outline a procedure the technician could use to validate the correct gauge readings for the fuel level.

Pressure Sensors

FIGURE 17-4 This normally closed hydraulic or air pressure switch is opened with pressure and closed when pressure is too low. A calibrated internal spring will allow the switch to complete a ground circuit when pressure drops below a preset amount.

FIGURE 17-5 All warning lights will illuminate during the initial key-on period, to ensure the bulbs are functioning. The engine warning and stop lamp will blink OEM (original equipment manufacturer) flash codes when prompted by a diagnostic switch. **A.** Blink code diagnostic switch. **B.** Stop engine light red. **C.** Warning light—yellow.

Mechanical Gauges

Mechanical direct-reading gauges are not electrical, since they depend on cables, air, or fluid pressure to operate. Speedometers operated by cables and oil pressure read by bourdon tube gauges are examples of direct-reading mechanical gauges.

Sending units are used in electrical instrumentation to convert pressure and temperature into analog signals used by instrument gauges. Sending units differ from sensors in that they are electromechanical devices, whereas sensors are non-mechanical electronic devices. Pressure and temperature switches will often operate warning lights.

Bimetallic Gauges

Bimetallic gauges work by heating metal strips, which bend and move a gauge pointing needle (**FIGURE 17-6**).

FIGURE 17-6 Bimetallic gauge operation. Bending of the bimetal strip changes the position of the pointer.

Two dissimilar pieces of metal are bonded together into a strip, much like a circuit breaker, and they expand at different rates as when heated. Heat produced through resistance of a wire coil wrapped around the bimetal strip is proportional to current flow (**FIGURE 17-7**).

Current supplied by a sending unit changes the position of the pointing needle attached to the bimetal strip. Because machine voltage fluctuates with changes to electrical loads and charging system output, a voltage regulator is required to maintain consistent gauge readings. Commonly, another bimetallic-type device will hold voltage supplied to gauges and sending units to between approximately 5 and 10 volts. The instrument voltage regulator (IVR) will use a bimetal arm with a set of breaker points that open and close rapidly when heating and cooling, in order to maintain instrument gauge voltage.

FIGURE 17-7 Construction and operation of a bimetal fuel gauge. Dissimilar metals expand at different rates when heated. The rheostat in the fuel tank controls current flow through the heater element.

D'Arsonval Gauges

D'Arsonval gauges are a type of electromagnetic gauge that moves a pointing needle directly proportional to current flow through an electromagnet attached to the pointer (**FIGURE 17-8**).

Needle deflection is controlled by current in the coil, which changes magnetic-field strength interacting with the fields of two permanent magnets fixed on either side of the coil. A larger

FIGURE 17-8 D'Arsonval movement gauges use a coil mounted between two permanent magnets. Changes in the coil's magnetic-field strength pull it toward one magnet and push it away from the other, causing rotation of the needle movement. A small light spring can return the pointer to a rest position.

flow of current produces a magnetic field that opposes one of the permanent magnet's fields and is attracted to another. Voltmeters are an example of a gauge that can use D'Arsonval movement. Other gauges using a D'Arsonval movement require a voltage regulator to maintain consistent readings.

Two- and Three-Coil Movements

Variations of the D'Arsonval movement use a pointer with a permanent magnet rather than an electromagnet. Two or three electromagnetic coils surround the pointer to rotate the gauge. Two-coil designs require a voltage regulator to maintain consistent readings, as charging voltage varies, while three-coil designs generally do not (**FIGURE 17-9**).

Both these gauges are more accurate than D'Arsonval movement gauges and are unaffected by temperature. In the two-coil gauge design, the field coils are wound in series but in opposite directions. This places a north and south pole on maximum and minimum reading sides of the pointer's magnet. Regulated ignition current is supplied to one end of the series coil, and the ground pathway is through a sending unit. Increasing current flow through the coil will intensify the forces of repulsion in one coil and attraction in the other. Pointer rotation takes place as magnetic-field strength increases or decreases proportional to current flow in the coils. In the **three-coil gauge** design, a coil is placed at the minimum and maximum reading ends of the pointer's rotation (**FIGURE 17-10**).

FIGURE 17-9 Two-coil gauges are connected to battery + in parallel but wound in the opposite direction. The ground of one coil is connected to a rheostat that changes the current passing through the coil and its magnetic-field strength. The needle is pulled to the coil with the strongest magnetic-field strength.

FIGURE 17-10 Operation of a three-coil design gauge. The bucking coil progressively cancels the effect of the minimum reading coil as less current passes through the sending unit.

A third coil, called a bucking coil, is placed between the minimum and maximum gauge reading. Ignition current passes through all three coils, which are wound in series. Two ground connections are supplied to the coil. One is at the end of the maximum coil, allowing all current to pass through all three coils. The other is a ground supplied through a sending unit. This ground connects to the gauge at a point between the minimum and bucking coil. Current flow passes through all three coils when resistance through the sending unit ground path is high. The maximum reading coil exerts the greatest force to pull the pointer magnet in that direction, as the minimum reading and bucking coil are wound in opposite directions to cancel each other's magnetic field. However, decreasing resistance through the sending unit permits more current to pass through the minimum reading coil, which progressively cancels out the effect of the bucking and maximum reading coil with decreasing sending unit resistance.

Stepper Motor Design

By far, **stepper motor gauges** are the most commonly used gauge technology in late-model instrument gauge clusters. The use of stepper motors to rotate pointers for analog displays bypasses the problem of inaccurate readings from bimetallic and electromagnetic coil gauges caused by voltage fluctuations, temperature changes, and oil leaks from fluid-dampened gauge clusters. This inexpensive and unique category of electric motors can precisely control the pointer rotation by dividing full motor rotation into a large number of fine resolution steps. Most gauges have 3,060 possible steps

of positions between zero and full-scale deflection. Speedometers, odometers, pressure, and temperature gauges will use stepper motors to accurately display data. Stepper motors are brushless, DC electromechanical devices that generally use a permanent magnet shaft surrounded by two or more pairs of electromagnetic coils. Energizing one or more of these field coils will cause the shaft to align with the coil, pulling and holding the shaft in a stationary position. To continue rotating the shaft, another field coil next to the first is energized, causing the shaft's magnet to realign with the energized coil while the first coil is deenergized. Alternately energizing and deenergizing coils in a particular sequence moves the shaft in the desired direction in incremental steps. A large number of steps make the gauge appear to move in a smooth motion. The speed of rotation can be precisely controlled by changing the rate at which coils are switched on and off. A particular sequence of energizing and reenergizing of coils will pull and/or push the shaft in a full 360 degrees of rotation, but full rotation is unnecessary because the gauge sweeps through only 270 degrees for its minimum and maximum range. During start-up, gauge calibration and operation are checked by having the gauge sweep through its entire range, returning to zero, and then rotating to the correctly sensed position. A Hall-effect sensor and magnet built into the gauge are sometimes used to identify the full range of needle sweep.

Unipolar Stepper Motor

Two common types of stepper motors are used for instrument gauges: unipolar and bipolar motors. The unipolar stepper

FIGURE 17-11 Unipolar motor operation. **A.** The upper electromagnet (1) is activated, and the teeth of the central cog line up accordingly. **B.** The upper electromagnet (1) is deactivated, and the right one (2) is turned on. The closest cog teeth then jump to line up with this new magnetic field. This causes a step turn of 1.8 degrees if there are 200 step turns. **C.** The right electromagnet (2) is deactivated and the lower one (3) is turned on. The cog teeth then jump to line up with the bottom electromagnet. This causes another step. **D.** The lower electromagnet (3) is switched off and the left (4) electromagnet is switched on. The cog teeth then jump to line up with the left electromagnet, producing another step.

motor is identified by its five or six wires that connect four field coils. The ends of all the coils have one common connection that is supplied power, giving the motor the name unipolar stepper because power is always supplied to this single point to form magnetic poles in the field coils. The other coil ends are connected to driver circuits of a microcontroller. Using digital logic and microcontrollers, the field coils are switched on and off to rotate the motor forward or backward or to hold the shaft (**FIGURE 17-11**).

TABLE 17-1 shows the steps used to rotate a four-pole unipolar stepper motor. A constant battery positive or ground is supplied to the coils while a ground or positive current source is switched on and off to rotate the motor.

Bipolar Stepper Motor

Unlike unipolar steppers, bipolar stepper motors have no common connection between the motor stator. Instead, coils used in the stator are independent sets of coils that enable a change in current polarity (**FIGURE 17-12**).

By measuring the resistance between the lead wires, bipolar steppers are distinguished from unipolar motors since any

TABLE 17-1 Steps Used to Rotate a 4-Pole Unipolar Stepper Motor

Step number	Coil A	Coil B	Coil C	Coil D
1	5-volts	0	0	0
2	0	0	5-volts	0
3	0	5-volts	0	0
4	0	0	0	5-volts
5	5-volts	0	0	0

two pairs of wires will have equal resistance and no continuity between the coils in the stator (**FIGURE 17-13**).

Like unipolar motors, digital logic will energize the motors to produce desired motor travel characteristics. Torque is increased in bipolar motors at the expense of finer steps to produce rotation. Adding a second wire to each pair of coils in a unipolar motor allows half the coil to be energized, producing

FIGURE 17-12 Some bipolar motor designs use permanent magnet rotors. Bipolar motors are capable of reversing current polarity across their coils, while unipolar motors cannot.

FIGURE 17-13 A variety of wiring combinations exist for various stepper motors. Stepper motor coils are energized one at a time or in pairs to increase torque output. Exhaust gas recirculation (EGR) motors are another application on diesel engines for stepper motors.

even finer steps of rotation. Directional changes are capable in both unipolar and bipolar stepper motors.

Digital CAN Gauges

Digitally driven gauges, networked gauges, or intelligent gauges are designed to display information broadcast over the communications. These gauges, which can use stepper motors or LCD/LED displays, are wired directly to the CANbus (controller area network bus). Circuits inside the gauges eliminate

the need for a graphic label, interface module, or other device to drive them. Custom programming of the gauge at the manufacturer level is required to translate the programmable group message (PGM), which contains messages for multiple gauges in order to provide the proper interpretation or user-defined values (**FIGURE 17-14**).

Entire instrument clusters rich with data are now operated using CAN-driven data generated by control modules throughout the machine. Just two wires connecting the instrument panel gauge clusters to the CAN network are all that is necessary to display machine data and gauge information, provide fault codes, and display warning lamps.

FIGURE 17-14 A CAN-driven gauge will display data available on the machine network. CAN displays are both input and output devices. Menu buttons allow the operator or technicians to access a variety of data sets.

Speedometers

Speedometers electronically measure the driveshaft, wheel, or transmission shaft speed by counting a series of electrical pulses produced per mile or kilometer of distance traveled. A variable reluctance sensor is a toothed metal wheel typically placed at the transmission shaft to measure drive line speed, which corresponds to road speed.

Earlier equipment enables customized calibrations for the various chassis pulse counts using **data inline package (DIP) switches**. These are small slide switches located at the rear of the speedometer head, placed in either the on or off (1 or 0) position. Circuits inside the speedometer convert the number of received speed sensor pulses to a pulse count per mile that varies with wheel speed.

While DIP switches are set at the factory for an original equipment pulse count, switches may need to be reset if the drive line components, such as tire size or rear axle ratios, have changed from those originally installed on the machine. Procedures to adjust the DIP switches are outlined in service manuals and usually involve plugging variables for tire size or rolling radius and rear axle into a formula to determine the settings (**FIGURE 17-15**).

Inaccurate or fluctuating speedometer readings can be caused by other systems associated with the speedometer signal. Interference can originate from the engine/transmission signals and controllers, the alternator, and other charging system components. Alternating current ripple from the alternator can also induce electrical interference with speedometer signals.

Manufacturers currently use unique, proprietary software and diagnostic and maintenance tools that enable access to the machine speed settings within certain limits to accommodate changes in tire size or rear axle ratio and to adjust the speedometer calibration.

FIGURE 17-15 A speedometer with DIP switches is used to calibrate the display with pulses per mile from the speed sensor. Tire sizes and rear axle ratio require different DIP switch settings.

► TECHNICIAN TIP

Most speedometers have tolerances of $\pm 10\%$ due primarily to variations in tire diameter. Sources of error due to tire diameter variations include wear, temperature, pressure, machine load, and nominal tire size. Machine manufacturers usually calibrate speedometers to read slightly higher than actual road speed by an amount equal to the average error. This practice eliminates potential liability caused by speedometers that display a lower speed than the actual road speed of the machine. GPSs can be used to validate the calibration of a speedometer. Failures or interference with signals from the variable reluctance speed sensor are best analyzed using a wave-form meter. Comparing the observed signal pattern with known good quality wave forms can identify potential problems with the speed signal.

Tachometers and Odometers

Tachometers used to observe engine speed are constructed and operate almost identically to speedometers. Variable reluctance or Hall-effect sensors are used to generate signals to the tachometer head. The engine control module (ECM) counts all of the pulses from both the speedometer and tachometer to track overall distance traveled by machine and engine. Several times per second in networked machines, the ECM sends out a packet of information consisting of a header and speed-distance data. The header is identifying the accompanying data packet as a distance or speed reading that can be read by the tachometer or odometer. Distance traveled may also be stored in an instrument cluster control module. In networked machines, trip values stored in the ECM are compared with an instrument cluster control. This means that if an attempt is made to roll back the odometer, the value stored in the ECM will not correspond and will generate a fault code.

► Operator Information Screens

K I 7002

Most operator information displays offered in machines today display engine rpm, fluid levels, fluid temperatures, warning lights, transmission speed and direction, and some basic diagnostic information or codes on liquid crystal displays (LCDs). Enormous amounts of other information systems can be added to the list: object detection warning, fuel consumption, action warning, outside temperature, telematics, and after treatment information. A variety of options are available to navigate the operator's information display menu: odometer buttons, the turn-signal wiper stalk, or a touch screen.

Liquid Crystal Display

LCDs use a compact passive display technology and consume little current to operate. Passive display means that LCDs do not emit light but instead use ambient light around the display to reflect images. The displays are made of several layers. An important one contains the liquid crystal, which is an organic substance having a liquid form with a crystal molecular structure (**FIGURE 17-16**).

The liquid is made of rod-shaped molecules that are arranged in a parallel lattice-like structure—a property that makes crystal transparent. However, an electric field can be used to control arrangement of the molecules. To do this, LCD

FIGURE 17-16 LCDs do not emit light but reflect it. Electric current passing through layers of glass distort liquid crystals, which allows light to either pass through and be reflected from the rear polarizer (on) or block light and reflect light from the top polarizer (off). Light reflected from the rear polarizer hits a dark gray or black surface. Light reflected from the top polarizer layer is silver or light gray.

glass has transparent electrical conductors embedded into each side of the glass, which are in contact with the liquid crystal fluid. Made of indium-tin oxide (ITO), the liquid crystal molecules will rotate in the direction of the electric current when it passes through the glass. When this happens, incoming light can pass through the glass and is reflected off a silver, gray, or black reflector surface, called the rear analyzer. What is observed is a black or gray character on a silver background taking the shape of the LCD cell. When the current is switched off, the molecules revert back to a twisted, light-blocking structure that reflects

ambient light back to the observer, resembling a light gray or silvery image. Using multiple selectable current pathways through the glass and selectively applying voltage to the current paths, a variety of patterns can be achieved.

Resistive Touch Screens

All touch screen devices digitize the input from finger contact using an x - y coordinate. This means that there is a unique input determined by how far the contact is from the horizontal screen bottom or vertical side (**FIGURE 17-17**).

FIGURE 17-17 Resistive-type touch screens plot the location of a finger or stylus by plotting coordinates using a resistive film screen material. A unique resistance value on a screen is generated by pressing one current-carrying resistive film against another.

FIGURE 17-18 Operation of a capacitive touch screen.

Two types of technology used to sense the coordinates are capacitance and resistive touch screens.

Resistive touch screens are composed of two flexible transparent sheets lightly coated with an electrically conductive yet slightly resistive material. The sheets are separated by an air gap or microdot that closes like a switch when finger, object, or other pressure is applied to the screen. A unique voltage value is sensed by conductors placed at the x - y coordinate edge of the screen. Signal voltage is translated into coordinates, and an input command goes to the screen microcontroller. The resistive touch screen's advantages include its low cost, scratch resistance, durability, and capacity to operate in all climate conditions. Input can be made using either a finger or stylus.

Capacitance Touch Screens

Capacitance touch screens use two transparent plates as well. However, they use only one electrically charged layer that is typically a glass panel with a transparent coating of indium metal (**FIGURE 17-18**).

When a finger is placed on the screen, it draws electrons from that specific point on the charged plate by changing the dielectric strength of the air gap, electrically separating the plates. A unique voltage signal is sensed by conductors on the x - y axis of the screen. The signal varies in strength from left to right and up and down, proportional to where the contact was made. A microcontroller works out the x - y position based on the voltage signal caused by a change of plate capacitance produced by finger contact. If gloves—such as thin latex examination gloves, which prevent electron movement—are used, the screen will not operate. Nor will it operate if a stylus is used, and the screen is confused under wet or high humidity conditions. Capacitance-type touch screens, however, permit dual-finger touch processes and do not require as much pressure as resistive screens.

► Troubleshooting Instrument Gauge Problems

K17003

Technicians must be able to accurately diagnose gauge problems. A guide to troubleshooting gauge problems is in **TABLE 17-2**.

Sending Units

Sending units are electromechanical devices that convert pressure or fluid level into a variable voltage signal. Sending units are different from sensors, which are low-voltage electronic devices with no moving parts. Most sending units are a variable resistive type (**FIGURE 17-19**).

FIGURE 17-19 A rheostat used for the sending unit of a fuel tank.

TABLE 17-2 Troubleshooting Instrument Gauge Problems

Symptom	Possible Cause	Diagnostic Strategy
Gauges do not repond with a prove-out sequence when ignition is switched on.	Missing or broken ignition or ground wire	Check for power and grounds to instrument cluster.
	Blown fuse	Check fuses and breakers.
Erratic gauge readings	Defective stepper motor	Continuity checks of stepper motor.
	Loose connections at sender unit and/or gauge	Verify connections.
	Poor, loose, or resistive grounds	Measure resistance of sending unit and compare with specifications.
	Defective sending unit or gauge	Evaluate gauge during prove-out. Stepper motor gauges should smoothly sweep from min. to max. values then to minimum before moving to sensed value.
Gauge stays at minimum or maximum value all the time (i.e., fuel empty, no oil pressure, low coolant temperature)	Sender unit wire disconnected or open circuited	Verify oil pressure with master mechanical gauge. Visually check fuel tank level. Verify engine temperature using an infrared thermometer.
	Sender unit wires shorted to ground	Remove sender wire. Check harness isolate shorts to ground and repair.
	Sender unit defective, (i.e., broken unit, missing or leaking float, internally shorted to ground)	Measure resistance of sending unit over its full range. Check float.
	Defective gauge	Supply a calibrated resistance to sending unit lead to evaluate gauge. Ground out sending unit wire to observe whether gauge moves. Disconnect sending unit wire to observe whether gauge moves.
No data on CAN instrument gauge display	Pinched, shorted, or open CAN bus to instrument cluster	Check CAN signal to clusters using oscilloscope. Measure CAN power and ground with voltmeter.
	Missing terminating resistors	Measure CAN signals using a voltmeter. Measure resistance of CAN line batteries disconnected.

The fuel tank sending unit, for example, uses a resistive wiper mechanism. An electrical whisker or brush moves along a resistor track depending on the fuel level. Low-voltage current originating through the instrument panel fuel gauge passes through the resistor track and then through to ground via the whisker. Oil pressure sending units use a flexible bellow also containing a whisker that passes along a resistor track. Pressure below the bellows moves the whisker along the resistive track to supply a ground (**FIGURE 17-20**).

Current to the sending unit is also supplied by the gauge. With less resistance in the sending unit, more current passes through the gauge to deflect the pointer between minimum and maximum readings. Temperature sending units use a wax pellet similar to the design of a coolant thermostat. As temperature changes, the wax pellet will expand or contract. A disc over the wax pellet acts like a whisker to change the resistance of the current pathway through an internal resistive track. Electronic modules are available to convert variable voltage values into digital signals for use by digital gauges.

Diagnosing Sending Units and Gauges

Resistive-type gauges are quickly checked by opening the circuit to the sending unit or by grounding the sending unit lead. When a circuit is opened, circuit resistance becomes infinite and will move a gauge to either its minimum or maximum reading. If that does not happen, the circuit to the gauge or the gauge itself is defective. Grounding the lead wire to the sending unit should move the gauge to a maximum or minimum value too. The type of gauge construction—D'Arsonval, two-, or three-wire—will determine in which direction the gauge will move when opened or grounded. A gauge testing unit can evaluate gauge accuracy by supplying a resistance of known value to the circuit and then observing whether the gauge pointer is positioned where expected. The accuracy of a fuel gauge is ideally evaluated using this method. The resistance of a sending unit measured with an ohmmeter can determine whether its resistance is within the range expected for a given pressure temperature or liquid level (**FIGURE 17-21**).

FIGURE 17-20 Construction of a variety of sending units with two-coil gauges. Note the voltage regulator used to maintain consistent gauge readings when charging system voltage varies.

FIGURE 17-21 Measuring the resistance of a fuel sending unit.

It's important to verify the ground supplied to the sending unit is good, as this will interfere with sending unit resistance values. Some sending units are designed with two terminals, one of which provides a dedicated ground for the gauge circuit.

► TECHNICIAN TIP

Low or no resistance of a sending unit to ground through the engine block, transmission, or axle case is critical for accurate gauge operation. Undiagnosed resistive grounds can often lead to unnecessary replacement of sending units and gauges. Always check the continuity of a major component case or block-to-chassis ground as part of a diagnostic pinpoint test. The use of Teflon tape can also interfere with sending unit continuity. Use liquid thread sealer rather than tape to prevent thread leakage. Because gauges often operate at low voltage, never touch the sender lead to ignition +12 volt.

► Wrap-Up

Ready for Review

- ▶ Instrument gauges, warning lamps, and operator information centers enable the operator to monitor the machine's operating condition, the status of equipment, and safety systems.
- ▶ Warning lights provide easily understood information to alert the operator to potentially dangerous operating conditions.
- ▶ Mechanical switches, called sending switches, are used to indicate low fluid levels, low air pressure warning systems, or power divider engagement locks.
- ▶ Electronic switches found in electronic control modules are the most common way warning lights are illuminated in today's machines.
- ▶ To test the correct operation of a warning light, machines use a prove-out sequence in which the instrument cluster illuminates the warning lights for several brief seconds with the key on and engine off or during key-on engine cranking.
- ▶ Manufacturers use blink codes to provide fault code data.
- ▶ Gauge systems are designed to inform the driver about a developing problem by displaying a representation of a physical measure of system conditions (pressure, temperature, or fluid level).
- ▶ Common gauge systems are mechanical, bimetallic strip, electromagnetic, stepper motor, and digital display.
- ▶ For gauges to work accurately, they require voltage regulators to supply a steady current and smooth out variation from the alternator and from accessory systems being turned on and off.
- ▶ Stepper motors increase the precision of the pointer rotation on a gauge and can be either unipolar or bipolar.
- ▶ Most speedometers have tolerances of $\pm 10\%$ due primarily to variations in tire diameter. Sources of error due to tire diameter variations are wear, temperature, pressure, machine load, and nominal tire size.
- ▶ Today's machines include data displays that allow the operator to view engine rpm, fluid levels, fluid temperatures, warning lights, transmission speed and direction, and some basic diagnostic information. Many of these displays use liquid crystal technology.
- ▶ Touch screens can use resistive or capacitance touch technologies.
- ▶ Machines use a number of different types of gauge sending units, including thermistors and variable resistors.
- ▶ Electrical problems such as a blown fuse, faulty wiring, gauges, or sender units can result in faulty gauge readings.

Key Terms

bimetallic gauge A gauge in which two dissimilar pieces of metal are bonded together and expand at different rates when heated, thereby converting the heating effect of electricity into mechanical movement.

blink code A method of providing fault code data for a specific system that involves counting the number of flashes from a warning lamp and observing longer pauses between the light blinks.

capacitance touch screen A display screen that uses two transparent plates, one of which is electrically charged.

D'Arsonval gauge A type of electromagnetic gauge that moves a pointing needle directly proportional to current flow through an electromagnet attached to the pointer.

data inline package (DIP) switches A small slide switch located at the rear of the speedometer head placed in either an on or off (1 or 0) position.

prove-out sequence A sequence in which the warning lights for several brief seconds with the key on and engine off or during key-on engine cranking.

resistive touch screen A display screen composed of two flexible, transparent sheets lightly coated with an electrically conductive yet slightly resistive material.

three-coil gauge A gauge in which three field coils are wound in series, with a coil at minimum reading, one at maximum reading, and one between the two.

Review Questions

1. Which of the following statements about instrumentation is correct?
 - a. The type of displays, warning lights, and gauges differ widely among machines and manufacturers but break down into common gauge groups, sensing, and input systems.
 - b. Monitoring engine operation involves measuring the pressure and temperature of parameters of the lubrication, cooling, and air induction system.
 - c. Charging voltage and amperage of the electrical system, fuel level, air pressure, engine, and machine speed are other common gauge systems.
 - d. All of the choices are correct.
2. Which of the following is the most common method of illuminating warning lights in today's machines?
 - a. Voltage drop circuits
 - b. Pneumatic switches
 - c. Mechanical ground switches
 - d. Electronic switches
3. Which of the following statements about the prove-out sequence is correct?
 - a. In older machines, the ignition key will supply a circuit to provide a ground and/or positive battery voltage path to illuminate instrument warning lights.
 - b. In order to validate the correct operation of a warning light, the instrument cluster is designed to illuminate a bulb for several brief seconds with the key on and engine off or during key-on engine cranking.

- c. If the engine starts, the bulb may remain lit until proper operating conditions are met, such as when the correct oil pressure has been reached.
 - d. All of the choices are correct.
4. Which of the following is NOT a technology used with common gauge systems?
- a. Electromagnetic
 - b. Stepper motor
 - c. Bi-electrical
 - d. Digital display
5. Mechanical gauges depend upon _____ to operate.
- a. cables
 - b. air pressure
 - c. fluid pressure
 - d. All of the choices are correct.
6. How much voltage is supplied to gauges and sending units?
- a. Between 0.5 and 1 volts
 - b. Between 1.5 and 2 volts
 - c. Between 3 and 4 volts
 - d. Between 5 and 10 volts
 - e. All of the choices are correct.
7. What is an example of a gauge that can use D'Arsonval movement?
- a. Ammeter
 - b. Voltmeter
 - c. Fuel pressure
 - d. Water temperature
8. Which of the following statements about two- and three-coil movements is correct?
- a. Variations of the D'Arsonval movement use a pointer with a permanent magnet rather than an electromagnet.
 - b. Two or three electromagnetic coils surround the pointer to rotate the gauge.
 - c. Two-coil designs require a voltage regulator to maintain consistent readings because charging voltage varies, but three-coil designs generally do not.
 - d. All of the choices are correct.
9. How many possible steps of positions do most stepper gauges have?
- a. 1,530
 - b. 2,400
 - c. 2,800
 - d. 3,060
10. The unipolar stepper motor can be identified by its _____ wires that connect _____ field coils.
- a. 2 or 3; 2
 - b. 4; 4
 - c. 5 or 6; 4
 - d. 7 or 8; 4

ASE Technician A/Technician B Style Questions

1. Technician A says warning lights can be built into gauges or mounted in a dedicated panel in the instrument. Technician B says warning lights require a power feed and ground for the light to illuminate. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says normally closed pressure switches opened with air or oil pressure provide a path to ground to illuminate a bulb. Technician B says normally opened pressure switches opened with air or oil pressure provide a path to ground to illuminate a bulb. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says that after the engine starts and the alternator begins charging, charging system voltage is applied to both terminals of a bulb. Technician B says the charging system indicator light is an example of a light operated through voltage drop. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
4. Technician A says the malfunction indicator lamp (MIL) and check engine lamp (CEL) will illuminate for approximately three to five seconds during engine start-up and then extinguish. Technician B says if there are active fault codes, the lights will switch back on after start-up. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says stepper motor gauges reduce the problems associated with inaccurate readings from bimetallic and electromagnetic coil gauges caused by voltage fluctuations. Technician B says stepper motors are brush-type DC electromechanical devices that generally use a permanent magnet shaft that is surrounded by more than two pairs of electromagnetic coils. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

6. Technician A says speedometers electronically measure the driveshaft speed by counting a series of electrical pulses produced per mile or kilometer of distance traveled. Technician B says two wires connecting the instrument panel gauge clusters to the CAN network are all that is necessary to supply the data necessary to display machine data and trip information, provide fault codes, and display warning lamps. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
7. Technician A says gauge senders output an electronic signal based on an electrical input. Technician B says electronic modules are available to convert variable voltage values into digital signals for use by digital gauges. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says electrical problems such as a blown fuse, faulty wiring, gauges, or sender units can result in a faulty gauge reading. Technician B says machines use only one type of gauge sending unit. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
9. Technician A says that if a gauge does not respond during a prove-out sequence, a blown fuse is the problem. Technician B says erratic gauge readings could be caused by resistive grounds. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
10. Technician A says you should use an ohmmeter when checking for smooth operation of a fuel sender unit. Technician B says the fuel sender unit should be reconnected to the fuel gauge to check for full-range operation only after removing it from the tank. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

CHAPTER 18

Principles of Machine Electronic Control Systems and Signal Processing

Knowledge Objectives

After reading this chapter, you will be able to:

- **K18001** Identify and explain the advantages of electronic signal processing over mechanical system control.
- **K18002** Identify and describe the operating principles of electronic signal-processing systems used in electrical system.
- **K18003** Identify and describe the types of electrical signals and associated terminology.
- **K18004** Identify and describe the functions, construction, and application of electronic control modules.

Skills Objectives

There are no skills objectives for this chapter.

► Introduction

Today's machine systems found on mobile off-road equipment are most often controlled by electronic systems, and technicians are just as likely to use a computer as they are to use a wrench to service them. Most machine systems cannot operate without complete or at least some degree of electronic control. This has not always been the case. Before the use of electronic controls, mechanical devices such as levers, springs, linkage, gears, cables, or bellows controlled system operation. Electronic systems using microcontroller- and microprocessor-based control now provide operational capabilities far exceeding any mechanical system capabilities and can do this with greater precision, efficiency, and reliability. The dominance and sophistication of electronic control makes skill development related to servicing this technology one of the most important priorities for successful technicians. Understanding the operating principles of electronic control systems is foundational for choosing diagnostic strategies, using service tools effectively, and making sound repair recommendations.

► Benefits of Electronic Control

K18001

Electronic control offers many benefits to today's mobile off-road equipment, including increased power and efficiency, enhanced reporting capabilities, telematics, increased safety, programmable features, and self-diagnostic capabilities.

Increased Power and Efficiency

Diesel engines were the some of the first machine systems transformed by electronic controls (FIGURE 18-1).

Engines had reached their limit of efficiency, and the next logical step was to apply electronic controls already used on gasoline engines. The immediate benefits of these refinements to engine operation are lower engine emissions, improved fuel economy, increased reliability, and enhanced performance. Smarter engines continue to deliver ever-increasing power from smaller displacements, quieter operation, and longer service intervals, in addition to needing less maintenance. The

increased costs of some of these features are offset through improved engine efficiency. Many of the electronic control systems have in fact lowered the cost of machine production while adding more features with improved operating benefits. In comparison to mechanical controls, electronic controls enable far greater flexibility to adjust fuel injection metering, injection rate, and timing over a large number of operating conditions. When engine operational problems leading to excess emissions do occur, self-monitoring and self-diagnostic capabilities of electronic controls can identify the problem, alert the operator, and revert to operating modes that minimize noxious emission production.

TABLE 18-1 shows the increase in power output per cubic inch of displacement and lowering of emissions achieved through advanced technology and electronic control of the fuel system.

Information Reporting Capabilities

Life cycle costs of operating machines with these engines is further reduced through the ability of the engine control systems to interface with tablets and Windows-based diagnostic and service software. Service technicians can access a wealth of diagnostic and service data much faster and with more precise detail than before (FIGURE 18-2).

Operational reports from the machine ECM extracted during scheduled maintenance intervals report details such as diagnostic fault codes, fuel consumption, idle time, emission system performance, and machine abuse statistics (FIGURE 18-3).

Telematics

In addition to the obtaining machine and operational information downloaded at scheduled maintenance intervals, ECM data can be collected and modified by other means (FIGURE 18-4).

When equipped with the correct machine interface devices, machine and engine diagnostics can be performed from distant locations. Telematics, a branch of information technology, uses specialized telecommunication applications for the long-distance transmission of information to and from a machine (FIGURE 18-5).

You Are the Mobile Heavy Technician

A number of machines have arrived at your shop with a list of apparently unrelated complaints: machine speed display that begin to bounce at 10 mph (16 kph), automatic transmissions that shift erratically, dozens of hydraulic codes for components and circuits that have no faults, and rough-running engines. On one of the machines, when performing some pinpoint tests with a digital multimeter, you accidentally set the meter to read alternating-current (AC) and not direct-current (DC) voltage. You are surprised to discover close to 4 volts of AC current are superimposed on the system's 12-volt DC current. Realizing that the only component that could produce AC current is the alternator, you disconnect the alternator and find the AC voltage has disappeared along with the unusual electrical system complaints. To repair the problem, the alternator is replaced and so are the machine's batteries, which all tested defective. As you prepare to document the diagnosis and justify the replacement of the parts on the work orders, consider the following questions:

1. What shop equipment could be used to capture and record the AC voltage signal frequency and waveform to document the problem?
2. Would the electronic control module (ECM) be processing the correct data from some sensor inputs if AC voltage accompanies the DC voltage inputs? Explain your answer.
3. After gaining the experience repairing these machines, what checks would you recommend in future for diagnosing electrical problems that may be related to electrical signal interference?

FIGURE 18-1 An overview of components used for the engine management system of a common rail diesel engine. Extensive use of electronics translates into precise control of combustion events for low emissions, superior performance, and fuel efficiency.

For example, when machines are equipped with radio-, satellite-, or cellular-based communications, a technician or equipment manager can remotely monitor any information about the machine, engine, or product the machine is carrying that is available from the machine network data link connector. Messages can be sent back and forth between the machine and a central location. For example, if the amount of fuel consumed is above normal, necessary steps can be taken to rectify equipment or operator error. A GPS can report machine location to an equipment manager, as well as log hours of run time. A fault code can be evaluated to determine whether immediate repairs are needed. For large operations, short-range wireless technology allows diagnostics and the programming of machines when they need a service or program update for increased productivity.

SAFETY TIP

The use of electronic engine and machine management provides for enhanced machine and occupant safety and security. If a machine's load is in danger, sensors and the machine control system can alert the operator. Engine systems can be monitored for operating conditions that have destructive potential. Low oil pressure, high intake, or coolant temperatures are commonly monitored conditions that can initiate an adaptive response to prevent catastrophic failure or damage. Dangerous operating conditions can trigger the engine to shut down, derate power, or simply warn the operator. The microprocessor powertrain control makes it possible to build in features that will protect the powertrain from damage due to excessive torque or speed as well. Hard braking and speeding are other measurable conditions monitored by management systems to ensure road safety.

TABLE 18-1 Increase in Power Output per Cubic Feet of Displacement

Engine Model	1988—7.3L IDI Diesel	2015—6.7L Powerstroke
Horsepower	180 hp	440 hp
Torque	338 ft/lb @ 1,600 rpm	860 ft/lb @ 1,600 rpm
NOX emissions	2.5 grams/bhp	0.07grams/bhp
Intake air flow @ 3,330 rpm	360 cubic feet/minute	732 cubic feet/minute
Exhaust flow @ 3,300 rpm	1,080 cubic feet/minute	1,499 cubic feet/minute
Fuel system	Mechanical distributor pump	Bosch piezoelectric injectors CP4.2 Common Rail Pump Electronic

FIGURE 18-3 Machine information is data produced from monitoring machine operation, such as fuel filter hours, transmission shifting patterns, idling characteristics, hard braking.

FIGURE 18-4 The instrument cluster can provide information to the operator about a variety of machine operating conditions.

Programmable Machine Features

Service technicians and operators can take advantage of programmable electronic controls. Programmable software provides flexibility to engines, transmissions, and implements for adapting to specific job applications, which enhances machine productivity, longevity, and operator comfort. Programmable changes may include things as simple as idle shut-down timers or maximum vehicle speed limits to adding safety interlocks that prevent the vehicle from moving if a door is open, a boom is raised, or outriggers are extended (FIGURE 18-6).

Power and torque-rise profiles are easily altered electronically. Depending on the application, it is beneficial to performance and fuel economy to have maximum torque appear over different rpm ranges. Instead of replacing an injection pump and turbocharger to change engine power characteristics, electronically controlled engines are recalibrated with new software instructions. In a few minutes with some keystrokes, a

FIGURE 18-5 Telematics uses satellite communication or cell phone technology to interface with the onboard machine network. Any network data can be read and sent to a remote monitor; reporting diagnostics and other service-related information.

FIGURE 18-6 A screenshot from Cummins' service information system, called INSITE, displaying some of the programmable engine parameters.

stock machine can be reprogrammed to operate for a customer-specific application.

Self-Diagnostic Capabilities

Electronic systems do not have many moving parts to wear out, but the systems can be complex. Diagnostics on electronically controlled machine systems can be performed easily, often

with fewer tools and in less time than on mechanical systems. When something goes wrong with a component or circuit, it can be extremely time-consuming and difficult to identify the problem without some built-in self-diagnostic capabilities. Built into electronic control systems is a self-monitoring function with capabilities to check the operation of circuits and electrical devices and determine whether voltages are out of range, whether the sensor data is likely correct, and whether the system is functioning properly. Problems are quickly identified as they occur. The presence of faults is communicated through the malfunction indicator lamps. An engine may even lose power or derate to prevent excessive emission production and engine damage and provide an incentive to have the condition repaired. Electronic service tools assist the technicians in performing off-board diagnostics—that is, perform pinpoint checks to precisely identify system faults. Software-based diagnostics deliver huge amounts of data about system operation, enabling service technicians to identify problems more quickly than they could with mechanical systems. Since modules, sensors, and actuators are more compact, they can be replaced quickly with minimal training and experience required.

► Elements of Electronic Signal-Processing Systems

K18002

At first glance, the operation of electronic control systems looks mysterious, using a variety of sensors, wires, electrical actuators, and electronic modules moved with invisible electrical signals.

However, to understand how electronic control systems operate, it is helpful to observe that any system functions can be broken down into three major divisions:

- sensing
- processing
- output or actuation (**FIGURE 18-7**).

Sensing Functions

Sensing functions collect data about operational conditions or the state of a device by measuring some value, such as temperature, position, speed, pressure, flow, angle. Sensors are devices designed to collect specific data in an electronic format.

Processing

Processing refers to the control system element that collects sensor data and determines outputs based on a set of instructions or program software. Operational algorithms, which are simply mathematical formulas used to solve problems, are included in the software that determines the steps taken when processing electrical data.

Outputs

The outputs of a system are functions performed by electrical signals produced by the processor. These may be signals to operate anything, including a digital display of numeric or alphabetic information, current to operate solenoids or injectors, actuators, motors, lights, or other electromechanical devices (**FIGURE 18-8**).

FIGURE 18-7 All engine management systems process electrical signals in three distinct stages: data collection from sensor inputs; data processing inside an ECM; and output devices, which are electrically operated.

FIGURE 18-8 Three stages of signal processing. Sensors form input signals, and software-controlled microprocessors are used to make decisions after interpreting data, while electrically operated output devices carry out instructions of the processor.

► Types of Electrical Signals

K18003

Before looking at the elements of the electronic management system, it is first important to look at types of electrical signals used in information processing systems (**FIGURE 18-9**).

There are three types of electrical signals commonly used as either inputs or outputs in electronic engine control applications:

- analog
- digital
- pulse-width modulation (PWM).

Analog Signals

An **analog signal** is electric current that is proportional to a continuously changing variable. Analog signals then will have a changing value of voltage, amperage frequency, or amplitude. For example, temperature changes continuously. A thermometer measuring temperature change can represent every possible temperature with the movement of liquid in a glass or a hand on a dial. An analog electrical signal would represent the smallest change in temperature proportional to the movement of liquid or hand on the dial.

FIGURE 18-9 Electrical signal waveforms of two basic types of electrical signals: digital and analog.

Measurement of alternating electrical current is another example of an analog signal. Variable-reluctance-type sensors, such as transmission output shaft speed or some engine position sensors, will produce an alternating current. Changing shaft speed or engine speeds will continuously alter the

FIGURE 18-10 The signal voltage from this throttle position sensor is a type of analog data. An infinite number of values for voltage exist between idle and wide open throttle.

frequency of current polarity change that is leaving the sensor. The intensity of the voltage will further continuously vary with speed.

A throttle position sensor is another example where analog data can be collected. The electrical signal produced by the sensor varies proportionally to pedal angle. A continuously changing voltage output from the sensor will vary with the driver input (**FIGURE 18-10**).

Outputs can be analog as well. The intensity of a light or sound from an output device, such as a lamp or speaker, can be reproduced by varying the voltage and frequency of an electrical signal. A light is dimmed or brightened by increasing or decreasing current to a bulb. An analog signal representing sound produces loudness and pitch by varying the voltage and frequency current to a speaker.

Digital Signals

In contrast to analog signals, **digital signals** do not vary in voltage, frequency, or amplitude. Instead, they are electrical signals that represent data in discrete, finite values. This means that the data is broken down into separate or smaller meaningful values. For example, the movement of hands on an analog clock will represent time in every possible value. However, a digital watch represents time in infinite values, such as seconds. A digital multimeter represents data the same way. The numerical display for an electrical measurement is represented as a fixed number (**FIGURE 18-11**).

In contrast, an analog meter would measure the same electrical value using a sweeping needle on a scale. A more common understanding of digital signals describes them representing data using only two conditions or values. This can be on or off, yes or no, 1 or 0, open or closed, up or down, etc. Binary code is an example of a digital signal. Every number from 0 to infinity and the letters of the alphabet are represented by a combination of 0s and 1s. Binary code easily lends itself to use in microprocessor circuits, where processing large amounts

FIGURE 18-11 This digital multimeter data represents resistance as a fixed, precise value. Smaller changes in resistance—several places to the right of the decimal point—are not easily measurable without the meter.

of alphabetic or numerical data, represented in strings of 0s or 1s, is performed.

Computerized powertrain management systems process information electronically using digital signals and binary code. This means that all information, whether analog or alphabetic, is converted into 1s and 0s. Using long strings of 1s and 0s may seem cumbersome, but just as Morse code tapped out on telegraphs could send information using only dots and dashes, the 1s and 0s of binary code can satisfactorily convey all kinds of information (**FIGURE 18-12**).

The difference between digital and Morse code is in the speed and accuracy of electronic processing. Processing millions and billions of 1s and 0s per second is something digital electronics can do to compensate for the cumbersomeness of using only 1s and 0s to communicate alphanumeric data.

FIGURE 18-12 A bit is the smallest piece of digital information that is either a 1 or a 0. A byte is a unit of 8 bits. Binary code represents letters and numbers in strings of 1s and 0s. Digital data can be represented as 0s and 1s.

Bits and Bytes

A **bit** is a shortened term for binary digit. This is the smallest piece of digital or binary information and is represented by a single 0 or 1. As illustrated in Figure 18-12, a **byte** is a combination of 8 bits.

The speed data that is processed in the engine control module, also called ECM or ECU (engine control unit), is measured in bits. The number of bits it can process during one central processing unit (CPU) clock cycle classifies powertrain ECMs and computers. Desktop or laptop computers often use 64-bit processors. A Pentium IV processor is 32 bits, whereas a late model ECM will have 16-bit or 32-bit capability. A 3.0 MHz processor will have 3 million clock cycles per second, which means a 32-bit processor processes 96 million bits of data per second. While the clock speeds and bit size of the processors in an engine ECM are smaller than they are in an average desktop, so is the programming code. The capabilities of an engine ECM may appear to lag a personal computer (PC), but the PC operates using hundreds of complex software programs. An engine, implement or powertrain control microprocessor that operates using only one program with much simpler software code to process information and produce output signals has enormous processing capability (**FIGURE 18-13**).

Today's machine processors have many times the digital processing capabilities of the onboard computers used to send Apollo rockets to the moon.

Serial Data

While discussing binary code and digital signals, it is useful to understand what serial data is. The term "serial data" originates from the way data is transmitted. It is in series, one bit after another along a single or pair of wires. When serial digital data is transmitted using a pair of wires, each wire will transmit a voltage pulse represented as a rectangular waveform. The wires will have a **differential voltage**, which means the voltage on the wire pair is a mirror opposite voltage when transmitting serial data (**FIGURE 18-14**).

A large differential voltage pulse represents a 1, while a small differential voltage pulse represents 0. Serial data is used to transmit information from one electronic module to another. Onboard data networks share information and control machine operation using serial data. More important to the technician, electronic service tools will use serial data to receive and send

FIGURE 18-13 This injector driver uses a 32-bit microprocessor and a number of microcontrollers to operate the fuel injectors in an engine.

C. Microprocessor. **D.** Memory. **E.** Microcontroller CAN transceiver.

FIGURE 18-14 A J-1939 datalink waveform showing data. Serial data transmits a series of 1s and 0s and has a digital form. The wide part of the waveform represents 1 or a string of 1s, while the narrow part of the waveform represents 0 or a string of 0s.

data. The rate at which serial data is transmitted is referred to as the baud rate. **Baud rate** refers to the number of data bits transmitted per second.

Analog to Digital Conversion

Because electronic processing units can only handle binary digital data, analog signals are converted to digital signals in a process called **analog to digital conversion** (**FIGURE 18-15**).

To convert analog signals to digital binary information, special circuits, known as buffers or analog to digital (AD) converters, are used (**FIGURE 18-16**).

To convert an analog signal, the electronics do a couple of things. First, the changing analog signal is sampled or divided up into segments, like a loaf of bread. In one second of time, the varying analog signal could be sampled 10, 100, or even 1,000 times (**FIGURE 18-17**).

Each of these segments will represent a specific voltage value. The finer or more accurate the processor wants the data to be, the more frequent the sampling rate, resulting in

FIGURE 18-15 Analog to digital conversion occurs in the input circuits of the ECM. Digital to analog signal conversion may also occur in the output circuits of the ECM.

FIGURE 18-16 An analog to digital (AD) conversion. An analog waveform is sampled and measured many times a second to generate a digital representation of the waveform. This process is identical to forming MP3 files. The more frequently the signal is sampled—128K, 256K, or more—the higher the signal quality.

better signal resolution or fidelity. Each of the segments will be assigned a digital value that is translated into a binary number. MP3 files are an example of an analog (wave file) to digital conversion. A digital wave file could be sampled 64K times a second or 128K times a second or more. Higher fidelity—the faithfulness to the original analog signal—is achieved at the more frequent sample rate.

► TECHNICIAN TIP

The current used in the electronic control systems is generally DC voltage. Radio frequency interference (RFI) induced into the system by magnetic fields of high-voltage power lines, radio transmitters, and even a microwave would be AC voltage. The signal-processing systems of ECM input conditioning circuits generally recognize and ignore these types of signals. This does not mean all electromagnetic interference

FIGURE 18-17 Analog signals from engine sensors are converted into digital signals for processing by the ECM.

goes unnoticed. Magnetic fields can induce voltage in signal wires and cause confusion for signal-processing units producing numerous types of unintended consequences.

Pulse-Width Modulation

An electrical signal that shares similar characteristics with both a digital signal and an analog signal is the pulse-width-modulated (PWM) electrical signal (**FIGURE 18-18**, **FIGURE 18-19**, **FIGURE 18-20**).

PWM refers to a signal that varies in “ON” and “OFF” time. That means it is digital in one aspect because it represents data

FIGURE 18-18 A pulse-width-modulated signal displayed on a graphing meter. Notice that the width of the pulses is similar.

in two states only—either on or off, or high or low. However, information is also conveyed by the amount of time the signal stays on or off. Time on or off is variable, which gives it an analog characteristic. The units for measuring pulse width are always expressed in units of time. Time is the measure of how long the signal is high or on.

To understand PWM, consider a light illuminated by a PWM signal. In one second of time, the light may be cycled on and off once. If the signal is applied for one-quarter of a second, the pulse width would be 0.25 seconds wide (**FIGURE 18-21**).

Common examples of devices using PWM signals are solenoids, injectors, and light circuits. A PWM signal is typically reported in milliseconds. PWM signals are commonly used as an output signal of an ECM. For example, the current supplied to a fuel injector or the pressure regulator of a HEUI or common

FIGURE 18-19 The longer the pulse width, the brighter the light, since more current flows through the circuit when pulse-width on-time lengthens.

FIGURE 18-20 Duty cycle is a comparison of on-time to off-time in one cycle. A cycle can be 1 second, 500 ms, or any length of time, but the cycle time is fixed when measuring pulse width.

FIGURE 18-21 The pulse width of the energization-time of an injector solenoid is measured in milliseconds.

rail pump is changed by varying the on-time of the electromagnetic control valve (**FIGURE 18-22**, **FIGURE 18-23**).

Output drivers of microprocessors are types of switches, usually switching transistors, which produce PWM signals to operate devices in an “ON” or “OFF” state (**FIGURE 18-24** and **FIGURE 18-25**).

The microprocessor device can also easily vary the duration-time of a driver opening and closing.

Sensors can input PWM signals, and solenoids can receive PWM signals. If a coil receives a PWM signal, it will be like getting an average voltage that is below the maximum voltage based on the amount of on-time or the duty cycle. Some manufacturers use sensors that use PWM signals to transmit data. One manufacturer that uses a lot of PWM signaling will pulse the signal at either 500 Hz or 5,000 Hz. PWM signals can come from position, level, pressure, and temperature sensors or can be an ECM output to a proportional solenoid. Caterpillar uses throttle position sensors that will transmit throttle position data using PWM signals. This type of data is unaffected by voltage drops encountered through long runs of wiring harnesses and multiple connectors between the sensor and ECM.

FIGURE 18-22 Varying the length of time electrical current energizes an injector solenoid will change the quantity of fuel injected into a cylinder.

FIGURE 18-23 The ECM will use the throttle position sensor as one of many sensors to calculate the pulse width applied to an injector solenoid.

FIGURE 18-24 An output driver of an ECM is usually a switching-type transistor. When the microprocessor applies a small amount of current to the base of the driver, a larger amount of current flows through the transistor to the output device.

Duty Cycle

Related to the term “pulse width” is duty cycle, illustrated in Figure 18-20. **Duty cycle** is another unit for measurement for PWM signals. While a pulse width is measured in time, duty cycle is measured as a percentage—on-time versus off-time. Duty cycle refers to the percentage of time that a PWM signal is high or on, in comparison to off-time (**FIGURE 18-26**).

One on- and off-time for a PWM signal represents one cycle. Duty cycle units are expressed as a percentage of cycle time. For example, if the pulse width is 0.8 seconds and the off-time is 0.2 seconds, a cycle is 1 second in length. This means the duty cycle is 80%. A 100% duty cycle means the signal is on all the time, while a 0% duty cycle is off. Another way of expressing this relationship is signal off-time versus on-time. A signal that is applied for three-quarters of a cycle is 75% duty cycle.

The difference between duty cycle and PWM is where the signal is used. Duty cycle is commonly used to measure the time a signal is applied to an output device operating at a fixed frequency, whereas pulse width measures a signal applied to devices operating at a varying frequency interval. For example, an engine may speed up and slow down, so the pulse width or time that an injector is energized will vary with speed. It is practical to measure actuation time only, since it is difficult to always know the frequency of a cycle—rpm, in this instance. Depending on engine speed, 10 or 20 injections may take place in 1 second, making it practical to measure only pulse width.

Consider, however, an electrohydraulic pressure regulator. This device will have a PWM signal applied to close a valve and increase pressure. Removing the signal will cause pressure to decrease. The time the signal is applied is broken into fixed time intervals. Therefore, a solenoid for this device may be on for 0.20 seconds out of fixed 1-second intervals. This would give it a pulse width of 0.20 seconds but a duty cycle of 20%. Pulse width could increase or decrease with a changing duty cycle (**FIGURE 18-27**).

To practically interpret system operation, a measurement of duty cycle is more meaningful.

Frequency

Frequency is the number of events or cycles that occur in a period, usually one second. The units of measure for frequency are **hertz (Hz)**, which is the number of cycles per second. A

FIGURE 18-25 The microprocessor controls the operation of the output drivers, which switch current flow on and off to electrical devices.

FIGURE 18-26 The measurement units for a PWM signal can also be a duty cycle. Duty cycle is expressed as a percentage of on-time versus off-time.

FIGURE 18-27 The duty cycle of this injection control pressure regulator for a HEUI fuel system is graphed and measured in duty cycle.

common application for frequency measurements is for alternating current. When current switches from positive to negative, one cycle has completed (**FIGURE 18-28**).

► Processing Function

KI8004

Processing electronic signals used in machine electronic control management systems is the function of ECMs. Referred to as the electronic control module (ECM), a microprocessor or microcontroller is the heart of the control unit. Made from hundreds if not hundreds of thousands of transistors contained in a semiconductor chip, the integrated circuit chips making up microprocessors and various controllers will contain a minimal amount of memory plus input and output circuits. Microprocessors have more memory, which gives them the capability to perform advanced calculations and follow software-based instructions (**FIGURE 18-29**).

In contrast to microprocessors, microcontrollers are less capable and carry out more limited and only specific functions built into the chip design. Microcontrollers are usually not programmable. An ECM will contain several types of memory, output drivers that control the operation of electrically operated devices such as injectors and relays as well as complex signal conditioning circuits for information processing functions. An ECM will contain a transceiver, which enables it to receive and send communication signals to an onboard network.

Alternating Current Flow

FIGURE 18-28 Frequency refers to the number of times a cycle occurs. Hertz refers to the number of times the cycle occurs in 1 second.

FIGURE 18-29 Integrated circuits used on a late model engine control module. **A.** Microcontroller; **B.** RAM (random access memory) and ROM (read-only memory); **C.** Flash memory; **D.** Microprocessor.

Several types of integrated circuit devices or “chips” are on board a typical ECM, which are essential to processing and ECM operation:

- the clock
- microprocessor
- microcontrollers
- analog to digital converted (AD converter)
- memory.

CPU Clock

The clock is an oscillator inside the microprocessor that controls how fast instructions stored in memory are processed (FIGURE 18-30).

It is like the drum beat that controls the pace of the work in the microprocessor. The clock speed is measured in hertz (or megahertz or gigahertz). With each cycle of the clock, the microprocessor will perform a set of tasks. Obviously, the faster the clock speed, the greater number of instructions processed per second.

Computer Memory

Several types of memory are used in an ECM, depending on its application. Some memory is used to store data from sensors since the ECM cannot process all sensor data simultaneously (FIGURE 18-31).

Other types of memory are required to store the instructions for operating the microprocessor. This memory would store software code to give the ECM its unique operational characteristics. Common categories of memory include

- read-only memory (ROM)
- random access memory (RAM)

FIGURE 18-31 Several types of memory support the processing functions of the microprocessor. **Programmable read-only memory (PROM)** stores specific operational instructions.

- programmable read-only memory (PROM)
- **electrically erasable programmable read-only memory (EEPROM)**
- flash memory or non-volatile RAM (NVRAM), which is a ROM/RAM hybrid that can be written to but which does not require power to maintain its contents.

Read-Only Memory (ROM)

Read-only memory (ROM) is used for permanent storage of instructions and fixed values used by the ECM that control the microprocessor. Information stored in the ROM would include algorithms such as how to calculate the pulse width for the injectors or the horsepower ratings for the machine. Other fixed values

FIGURE 18-30 The CPU clock controls the pace of calculations inside the microprocessor. Each device inside the microprocessor waits for the clock to signal the executions of a particular instruction.

would identify a maximum engine rpm, the temperature value for an engine overheat condition, the type of transmission, or the type of implement system. The ECM reads the instructions, but it cannot rewrite or change the instructions contained in ROM. ROM data is stored by the manufacturer. ROM memory is permanent and is not lost even if power to the computer is interrupted. This means the memory is **non-volatile** (FIGURE 18-32).

Random Access Memory (RAM)

Random access memory (RAM) is a temporary storage place for information that needs to be quickly accessed. Input data from sensors is commonly stored in RAM, awaiting processing by the ECM. RAM memory is both readable and writable. Most RAM memory is designed to be lost when power is interrupted, such as turning the ignition key off. That is why RAM is often referred to as temporary storage of memory. However, RAM can be stored in the ECM after the key is shut off. Non-volatile RAM holds its information even when the power is removed. **Volatile RAM** will be erased when the power is removed. If volatile RAM receives its power from the ignition key, its memory is lost when the ignition is turned off. If battery power is used to keep the RAM memory intact when the key is off, it is also known as **keep alive memory (KAM)**.

EEPROM and Flash Memory

Electrically erasable programmable read-only memory (EEPROM) was developed to allow manufacturers to change the software operating the ECM electronically rather than physically fix it into the ECM during its design and construction.

In recent years, flash memory, which is non-volatile EEPROM memory has become the most common type of memory used in ECMs. This is almost identical to the type used on a

USB memory stick. It has enormous shock resistance and durability and can withstand intense pressure, extremes of temperature, and immersion in water, which are conditions sometimes found in mobile off-road equipment. It also offers the convenience of easily reprogramming or recalibrating the ECM, also known as **flashing** or flash programming. Flash programming involves the installation of look-up tables in the ECM. Look-up tables are used by the ECM to solve mathematical problems called algorithms. An example of a simple algorithm would solve the problem of how fast the machine is traveling. The mathematical formula for speed would be distance/time. More complex algorithms involve calculating how much fuel to inject, when to inject fuel, or how long the injector should be energized. The look-up table provides specific data to help solve the problems for a specific engine.

► TECHNICIAN TIP

Microcontrollers and microprocessors are types of integrated circuits. The distinction between them is related to their capabilities. Engines, transmissions, and implement ECMs use microcontrollers. This is a special-purpose processor with limited capabilities, designed to perform a set of specific tasks. Reading sensor data and using logic gates to perform calculations and determine outputs required for the application such as energize a relay or injector solenoid are examples. Executing instructions stored in the memory of EEPROMs enhances the function of sophisticated microcontrollers. The controller's tasks, however, are limited to a specific application such as controlling the engine's operation. In contrast, a more sophisticated engine, implement, or other ECM use microprocessors are capable of executing logic and supporting a larger number of devices making up the ECM. Microprocessors will also use an operating system such as Windows, Linux, or Android, enabling the addition of multiple software programs to handle a larger variety of tasks.

FIGURE 18-32 Non-volatile memory means the information is not lost when power to the ECM is disconnected or the ignition is switched off. Keep alive memory refers to memory that is retained only due to a constant supply of current to the ECM when the ignition is switched off.

► Wrap-Up

Ready for Review

- ▶ Electronic systems using microprocessor- and microcontroller-based controls provide operational capabilities far exceeding any mechanical system. The dominance and sophistication of electronic control makes developing skills related to servicing this technology one of the most important priorities for successful technicians.
- ▶ Diesel engines were the first machine systems transformed by electronic controls. The immediate benefits of these refinements to powertrain control include lower engine emissions, improved fuel economy, increased reliability, and enhanced performance.
- ▶ Service technicians can access a wealth of diagnostic and service information much faster and with more precise detail than before.
- ▶ Telematics, a branch of information technology, uses specialized applications for long-distance transmission of information to and from a machine. Messages can be sent back and forth between the machine and a central location.
- ▶ The use of electronic engine and machine management provides enhanced machine and occupant safety and security.
- ▶ Programmable software provides flexibility to engines, transmissions, and implements to adapt to; adapting to specific job applications; and enhanced machine productivity, longevity, and operator comfort. Programmable features include idle shut-down timers, implement controls, maximum machine speed limits, and safety interlocks that prevent the machine from moving if the parking brake is on, a boom is raised, or outriggers are extended.
- ▶ Built-in electronic control management systems allow machines to check the operation of circuits and electrical devices, evaluate the rationality of data, and identify problems as they occur. The presence of faults is communicated through the malfunction indicator lamps, cab displays, electronic service tools, or Windows-based diagnostic software.
- ▶ Electronic control systems can be broken down into three major divisions: sensing, processing, and output or actuation.
- ▶ Sensing functions collect data about operational conditions or the state of a device by measuring some value, such as temperature, position, speed, pressure, or flow.
- ▶ Processing collects sensor data and determines outputs based on a set of instructions or program software.
- ▶ The outputs of a system are functions performed in response to electrical signals produced by the processor.
- ▶ Three types of electrical signals commonly used as either inputs or outputs in electronic engine control applications are analog, digital, and PWM.
- ▶ An analog signal is an electric current that is proportional to a continuously changing variable.
- ▶ In contrast to analog signals, digital signals do not vary in voltage, frequency, or amplitude. Instead, they are electrical signals that represent data as binary values, such as on or off, 0 or 1, yes or no, up or down, open or closed.
- ▶ Binary code is an example of a digital signal. “Bit” is a shortened term for binary digit. This is the smallest piece of digital or binary information and is represented by a single 0 or 1. A byte is a combination of 8 bits.
- ▶ Serial data is used to transmit information from one electronic module to another. Onboard data networks share information and control machine operation using serial data.
- ▶ Because electronic processing units can only handle binary digital data, analog signals are converted to digital signals by special circuits known as buffers or AD converters.
- ▶ An electrical signal that shares similar characteristics with both a digital and analog signal is the PWM electrical signal. PWM refers to a signal that varies in on- and off-time. A PWM signal is typically measured in milliseconds (ms).
- ▶ Duty cycle is another unit of measurement for PWM signals, and it refers to the percentage of time a PWM signal is on versus the time it is off. Duty cycle is commonly used to measure the time a signal is applied to an output device operating at a fixed frequency, whereas pulse width measures a signal applied to devices operating at a varying frequency interval.
- ▶ Frequency is the number of events or cycles that occur in a period. The unit of measure for frequency is hertz (Hz), which is the number of cycles per second.
- ▶ ECMs are microprocessors or microcontrollers that process electrical signals. Several types of integrated circuit devices on board a typical ECM are essential to processing and ECM operation.
- ▶ The CPU clock is an oscillator inside the microprocessor that controls how fast instructions stored in memory are processed. It is like the drum beat that controls the pace of the work in the microprocessor. The clock speed is measured in hertz (or megahertz or gigahertz).
- ▶ Several types of memory are used in an ECM, depending on its application. Some memory is used to store data from sensors because the ECM cannot process all sensor data simultaneously. Other types of memory

are required to store the instructions for operating the microprocessor.

- ▶ Common categories of memory include ROM, RAM, PROM, EEPROM, and flash memory (a ROM/RAM hybrid that can be written to but does not require power to maintain its contents).

Key Terms

analog signal An electric current that is proportional to a continuously changing variable.

analog to digital (AD) conversion The process when an analog waveform is sampled and measured many times a second to generate a digital representation of the waveform.

baud rate The rate at which serial data is transmitted.

bit The smallest piece of digital information, which is either a 1 or 0.

byte A unit of 8 bits.

differential Refers to the voltage difference on a wire pair when one wire's voltage is the mirror opposite voltage. A wide separation between the voltage pulses represents a 1 and a narrow separation represents a 0.

digital signals Electrical signals that represent data in discrete, finite values. Digital signals are considered as binary, meaning it is either on or off, yes or no, high or low, 0 or 1.

duty cycle The percentage of time a PWM signal is on in comparison to off-time.

electrically erasable read-only memory (EEPROM) Non-volatile memory technology that is used to store operating instructions or programming for an ECM.

flashing Reprogramming or recalibrating the ECM. Information is stored in the ECM's memory.

frequency The number of events or cycles that occur in a period, usually 1 second.

hertz (Hz) The unit for electrical frequency measurement, in cycles per second.

keep alive memory (KAM) Memory that is retained by the ECM when the key is off.

microcontroller A special-purpose processor with limited capabilities, designed to perform a set of specific tasks.

non-volatile memory Memory that is not lost when power is removed or lost.

programmable read-only memory (PROM) Memory that stores programming information and cannot be easily written over.

pulse-width modulation (PWM) An electrical signal that varies in on- and off-time.

random access memory (RAM) A temporary storage place for information that needs to be quickly accessed.

read-only memory (ROM) Memory used for permanent storage of instructions and fixed lookup table values used by the ECM that control the microprocessor.

telematics A branch of information technology that uses specialized applications for the long-distance transmission of information to and from a vehicle.

volatile memory A type of data storage that is lost or erased when the ignition power is switched off.

Review Questions

1. Which of the following is a benefit of electronic control?
 - a. Increased power and efficiency
 - b. Programmable features
 - c. Self-diagnostic capabilities
 - d. All of the choices are correct.
2. Which of the following statements about information reporting capabilities is correct?
 - a. The life cycle cost of operating machines with these engines is further reduced through the ability of the engine control systems to interface with tablets and both diagnostic and service software.
 - b. Service technicians can access a wealth of diagnostic and service data much faster and with precise detail than before.
 - c. Trip reports from the machine ECM extracted during scheduled maintenance intervals report details such as diagnostic fault codes, fuel consumption, idle time, emission system performance, and machine abuse.
 - d. All of the choices are correct.
3. Which of the following statements about safety is correct?
 - a. If a machine is involved in an accident, a call can be made to an emergency dispatch.
 - b. Engine systems can be monitored for operating conditions having destructive potential.
 - c. Hard braking and speeding are other measurable conditions monitored by management systems to ensure safety.
 - d. All of the choices are correct.
4. Which of the following is NOT correct concerning self-diagnostic capabilities?
 - a. Diagnostics on electronically controlled machine systems can be performed easily, often with fewer tools and in less time than they can be on mechanical systems.
 - b. The presence of faults is unable to be communicated through the malfunction indicator lamps.
 - c. Electronic service tools assist the technicians in performing off-board diagnostics—that is, performing pinpoint checks to precisely identify system faults.
 - d. Because modules, sensors, and actuators are more compact, they can be replaced quickly and with minimal training and experience required.
5. What type of data is collected by the sensing functions of the electronic control system?
 - a. Temperature
 - b. Pressure
 - c. Both A and B
 - d. Neither A nor B

6. What are some examples of outputs of the electronic control assembly?
 - a. Current to operate solenoids or injectors
 - b. Current to operate actuators
 - c. Current to operate lights
 - d. All of the choices are correct.
7. Analog signals can have a changing value of _____.
 - a. voltage
 - b. amperage frequency
 - c. amplitude
 - d. All of the choices are correct.
8. "Bit" is a shortened term for binary digit; a byte is a combination of _____ bits.
 - a. 2
 - b. 4
 - c. 6
 - d. 8
9. Which of the following statements about analog to digital (AD) conversion is correct?
 - a. Because electronic processing units can only handle binary digital data, analog signals are converted to digital signals.
 - b. To convert analog signals to digital binary information, special circuits, known as buffers, or analog to digital (AD) converters, are used.
 - c. Both A and B
 - d. Neither A nor B
10. Which of the following is NOT correct concerning duty cycle?
 - a. Duty cycle is another unit for measurement for PWM signals.
 - b. Duty cycle units are expressed as a percentage of cycle time.
 - c. A 100% duty cycle means the signal is off.
 - d. Duty cycle refers to the percentage of time a PWM signal is high or on in comparison to off-time.
- c. Both Technician A and Technician B
- d. Neither Technician A nor Technician B
3. Technician A says that telematics uses specialized telecommunication applications for the long-distance transmission of information to and from a machine. Technician B says that telematics is not capable of transmitting information on fault codes. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
4. Technician A says that technicians can take advantage of programmable electronic controls. Technician B says that power and torque-rise profiles cannot be altered electronically. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says that electronic control systems use a variety of sensors, wires, electrical actuators, and electronic modules moved with invisible electrical signals. Technician B says that the three major divisions of electronic control systems are sensing, processing, and output. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
6. Technician A says that processing refers to the control system element that collects sensor data and determines outputs based on a set of instructions or program software. Technician B says that operational algorithms are included in the software that determines the steps taken when processing electrical data. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
7. Technician A says that a bench signal is one type of electrical signal commonly used in electronic engine control applications. Technician B says that an analog signal is one type of electrical signal commonly used in electronic engine control applications. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says that, in contrast to analog signals, digital signals vary greatly in voltage, frequency, or amplitude. Technician B says that the binary code does not lend itself to use in microprocessor circuits, where processing large amounts of alphabetic or numerical data, represented in strings of 0s or 1s, is performed. Who is correct?
 - a. Technician A
 - b. Technician B

ASE Technician A/Technician B Style Questions

1. Technician A says that most machine systems operate with at least some degree of electronic control. Technician B says that understanding the operating principles of electronic control systems is fundamental for choosing diagnostic strategies. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says that diesel engines were the first machine systems transformed by electronic controls. Technician B says that smarter engines deliver ever-increasing power from smaller displacements. Who is correct?
 - a. Technician A
 - b. Technician B

- c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B
- 9.** Technician A says that serial data is used to transmit information from one electronic module to another. Technician B says that baud rate refers to the number of data bits transmitted per minute. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B
- 10.** Technician A says that a pulse-width–modulated electrical signal is an electrical signal that shares similar characteristics with both a digital signal and an analog signal. Technician B says that common examples of devices using PWM signals are solenoids, injectors, and light circuits. Who is correct?
 - a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B

CHAPTER 19

Onboard Networks Systems

Knowledge Objectives

After reading this chapter, you will be able to:

- **K19001** Identify and explain the purpose of onboard communication networks.
- **K19002** Identify and describe the construction of onboard communication networks.
- **K19003** Identify and describe the principles of onboard communication networks and multiplex communication technology.
- **K19004** Identify and explain the purpose, function, and application of distributed network control systems.
- **K19005** Describe and explain common diagnostic and service procedures for onboard machine networks.

Skills Objectives

After reading this chapter, you will be able to:

- **S19001** Check for completion of HD-OBD monitors for an engine.
- **S19002** Diagnose an HD-OBD-related fault code using diagnostic trees, appropriate code priority, appropriate flow charts, and pinpoint tests.
- **S19003** Perform a terminating resistor check.
- **S19004** Measure resistance of terminating resistors
- **S19005** Perform pinpoint voltage tests on a data link connector (DLC).
- **S19006** Check for shorts in the controlled area network.

► Introduction

Electrical systems on modern machines are becoming increasingly complex with the addition of a range of electronic and accessory systems, such as global positioning systems, Bluetooth systems, security systems, heated seats, and automatic climate control systems. Many of these systems are controlled by onboard computer systems. Increasingly, the electrical and electronic assemblies are interconnected through machine onboard data networks that require diagnosis. The technician requires an in-depth knowledge of these systems, including how they operate and are interconnected through the machine's onboard network. Diagnosing a machine fault requires the use of dedicated diagnostic tools that communicate with the machine's electronic control units. Connecting a diagnostic scan tool or a personal computer to a machine allows the technician to monitor data from sensors or control certain components' actions.

► Machine Onboard Networks

K19001

Today's mobile off-road equipment can have as many as 30 onboard electronic control modules monitoring and controlling the machine's systems, and these have increased the need for interaction between the machine's systems and components. For example, many systems must know the speed of the machine, such as instrument panel for the speedometer, transmission for gear selection, radio for speed-sensitive volume control, etc. (FIGURE 19-1).

Most often, the **typology** refers to the physical shape of the way a network is connected. Star network interconnections are shaped just like that—with star-shaped interconnections. It is the same way for most of the other sensors and systems as well.

Onboard machine networks are formed by connecting machine electronic control modules to one another to communicate and exchange information.

In concept, a machine network is somewhat like a social network, in which people are connected through websites or organizations that allow them to exchange information and collaborate to accomplish tasks or reach goals otherwise unachievable when unconnected. The idea of “the whole being

FIGURE 19-1 A networked system allows data to be sent over the system to all modules. The ones that need to know that information act on it, and the rest ignore it.

greater than the sum of its parts” applies to machine networks too. Extensive use of microprocessor-based controls applied to nearly every machine system can also be leveraged with network communication to provide a huge number of benefits not possible with modules and devices left unconnected.

Communication takes place between all the modules and devices connected to the network by using an electrical signal-processing strategy called **multiplexing**. **Multiplexing** simply refers to a concept where transmission of more than one electrical signal or message takes place over a single wire or pair of wires. In modern machines, thousands of messages are exchanged every second over onboard networks. Originally devised to eliminate bulky wiring harnesses, multiplex communication across modules and other network devices has made onboard networks practical. Networking between modules enables customization of a machine's electrical system, providing new operating features, enhanced diagnostic capabilities, and simplified repair procedures. A good

You Are the Mobile Heavy Equipment Technician

After arriving at a customer's yard for a service call, you are asked to diagnose the problem with a brand-new excavator. The machine will start and run, but the engine will not accelerate above idle speed. After the engine is started, a red warning light immediately flashes for 30 seconds before the engine shuts down. You perform typical visual inspections of the machine, inspecting the exhaust systems and wiring harnesses and checking for fuel, coolant, air, and oil leaks. According to the dash gauge and visual verification, the diesel exhaust fluid (DEF) tank is three-quarters full. Nothing seems amiss, but you realize that certain emission-related faults and engine-protection-system-related faults will produce these symptoms. Finding the fault that is specifically causing the severe engine power derate conditions and shutdown is challenging. Before performing any further steps, consider the following:

1. What are two procedures that can be used to retrieve fault codes, other than using OEM (original equipment manufacturer) or other types of diagnostic software?
2. Explain why the red engine warning lamp—the stop engine lamp—is flashing before the engine shuts down.
3. Are fault codes retrievable from this machine without OEM software? Explain your answer.

understanding of machine network construction, operation, and diagnostic techniques is critical for technician success.

► Network Construction and Classification

K19002

All networks have in common the concepts of interconnected modules, the use of serial data to enable digital communication between each module, and time division multiplexing as a communication strategy. However, there are a multitude of different networks types, each constructed differently, and each with its own unique characteristics.

The following are the most basic ways that onboard communication networks can be categorized:

1. **Typology**—typology describes how modules are connected to one another (FIGURE 19-2).

Most often, the typology refers to the physical shape of the way a network is connected. Star network interconnections are shaped just like that—with star-shaped interconnections (FIGURE 19-3).

Ring and bus networks are other common layouts of connection configurations for the channels exchanging data. The word “bus,” when used in network typology, describes a network connection that looks just like a bus route. These configurations feature two-way traffic and “bus stops” along the way, which are electronic control modules. The J-1939 network used by all off-road equipment uses a bus-type typology.

2. **The physical layer**—this refers to how the network hardware is constructed. For example, most networks use twisted wire pairs, but some use single wires, connect wirelessly, or even communicate using fiber optics. Standards exist for each type of network, such as how many nodes (number of modules) can connect, the type of connectors used, the lengths of the network wires.
3. **Network protocol**—this refers to the rules or standards used to communicate over the networks. Communication standards, device naming, definitions, fault code structure, and the physical layer are examples of network elements

FIGURE 19-2 The typology of a star network is shaped like a star.

governed by rules within a specific protocol. Mobile off-road equipment manufacturers have in the past used different protocols, many of which were written in the manufacturer's own proprietary language. Most of the mobile off-road equipment industry currently follows controller area network (CAN) standard protocol ISO11783 or SAE J1939 for agricultural and off-road equipment. Emission regulations legislate the use of network communication protocols.

4. **Centralized or distributed control**—networks may also be classified by (1) whether network operation is dependent on one master module directing the operation of several other slave module or (2) whether control of the machine's electrical system is shared among the machine's ECMs. Master-slave networks are referred to as centralized network control. The master module will send serial data to various other less sophisticated control modules, which contain only micro-controllers, to carry out instructions. The master module will make requests for information and sends commands to be executed by a slave module. A slave module responds only to requests by the master or central control module (FIGURE 19-4).

Distributed networks control machine operation and the electrical system using several to dozens of modules, all sharing information and sending output signals to electrical devices (FIGURE 19-5).

FIGURE 19-3 Network typology refers to the shape taken by the module interconnections.

FIGURE 19-4 A local interconnect network (LIN) uses a centralized control.

Most late-model machines have, in fact, multiple onboard networks using a combination of network types.

Networks are also constructed based on organizational priorities. Modules are grouped by a machine's area or function, such as those involved in engine, transmission, implement, climate control, instrumentation, entertainment devices, or body electrical control. Not all information has high priority. For example, information that affects machine or occupant safety, such as the hydraulic system, engine, or transmission, will not always share the same network as one involving data exchange for the climate control or onboard entertainment system. Still, some information needs to be exchanged between the networks. To enable communication between different onboard networks, a **gateway module** is used (**FIGURE 19-6**).

The job of this module, as the name suggests, is to translate communication between different networks that operate by using different protocols or speeds. Without the gateway module, access to networks through the DLC using electronic service tools would not be possible.

► Time Division Multiplexing

K19003, S19001, S19002

Communication between modules and network devices typically takes place over a single wire or pair of wires connected to each module. When paired together and connected in parallel to all modules in the network, the typology forming the communication pathway is called a **data bus**. Information is communicated digitally by using a series of 1s and 0s that represent numbers and letters. The digital communication used by onboard networks is similar to the electrical language of Morse code. Under this system, communication took place over a pair of telegraph wires using a series of dots and dashes. Both Morse code and onboard networks use what is called binary code, which means there are only two choices or types of information—0 or 1, dot or dash. The biggest difference is the speed at which the data is exchanged. Digital modules communicate much faster than Morse code; the increased speed is made possible through the use of digital electronics.

It may be puzzling to understand how only the same two wires connected to each module can send and receive information, apparently simultaneously, especially considering the enormous volume of data passing over the networks. If communication took place simultaneously, the positive and negative voltage pulses representing 0s and 1s would collide, canceling one another or generally becoming garbled, a lot like a noisy classroom when everyone is speaking at once and thus no one is understood.

However, using an electrical signal communication strategy called multiplexing overcomes the problem. The type of multiplexing used in onboard networks works by dividing the time available to each network module or device to transmit and listen to information. **Time division multiplexing (TDM)**

FIGURE 19-5 A J-1939 network uses distributed control of the machine's electrical system.

FIGURE 19-6 A distributed control network using a gateway module to translate between each network.

Image Provided As Courtesy of John Deere.

FIGURE 19-7 Time division multiplexing (TDM) is like a phone call where modules share a phone extension.

requires that the modules and other devices take turns, sharing the data bus communication pathway (**FIGURE 19-7**).

Only one module is allowed to talk, and all other modules must listen until it is their turn to talk. This should remind you of a well-ordered classroom where there is cooperation around communication and no one interrupts anyone else until they are finished speaking. Data transfer back and forth along the data bus does not take place simultaneously, but each device transmits and receives data by cooperating to time-share a common signal path (**FIGURE 19-8**).

The speed at which the data exchange takes place makes communication appear to occur simultaneously, although it does not.

Multiplexing Advantages

Multiplexed communication was originally designed to eliminate bulky wiring harnesses. Years ago, machines used a

point-to-point electrical connection method that meant switching on a single light required a circuit connecting the battery to a fuse, a switch, wires connecting the switch to the light, a connection to chassis ground, and an operator to decide to switch the light on. Regardless of where the light and the switch were located, wire connected each terminal of the light or lighting circuit. Every electrical device operated this way.

Understandably, point-to-point wiring technique results in very large, heavy wiring harnesses throughout the machine. Each connection in the circuit and length of wire also produce electrical resistance and a source of potential failure. Corrosion, loose connections, and chafed wiring were common electrical system failures, and the technique created a notoriously unreliable system that was difficult to troubleshoot.

Point-to-point wiring construction created unique problems for machines. Many feet of electrical wire were needed to control the electrical systems. Adding electrical relays to operate other simple 12/24-volt circuits built further complexity into the electrical system, which accounted for as much as one-half of engineering time and a large percentage of a machine's assembly cost.

To eliminate the problems created by point-to-point wiring and relay logic systems, bulky wiring harnesses were replaced by electronic, microprocessor-controlled lighting modules strategically positioned near the light circuits or other electrical devices.

Additional multiplexing advantages include the following:

- software control of the electrical system
- enabled onboard diagnostics
- ease of connecting electronically controlled accessories and features
- reduction in number of sensors.

Software Control of Electrical System

When using networks, electrical system complexity is absorbed by software instead of a huge array of hardwired components and circuit boards. The electrical system occupies

FIGURE 19-8 The rule of TDM multiplexing allows only one module to send information, and the remaining modules receive.

less space; is lighter in weight; and is easier to design, install, troubleshoot, and repair. An estimated two-thirds reduction in manufacturing cost and assembly time is achieved through the use of multiplexed network communication. The newest machine communication networks permit enhanced features and control of every electrical subsystem, from machine

lighting and cab controls (e.g., wipers, HVAC, windows) to every chassis electrical accessory. Multiplexed networks also allow precise electrical control of implement controls, transmissions, instrument gauges, air- and hydraulic-operated accessories, global positioning, and engine and transmission operations (**FIGURE 19-9**.)

FIGURE 19-9 A gateway module enables communication between different onboard networks.

Enabling Onboard Diagnostics

Legislation setting ever-lower limits on exhaust emissions required a greater level of precision in the operation of the diesel fuel injection system. Those lower limits are attainable only through the extensive use of electronics. The problem with diagnosing and repairing electronic systems in comparison to mechanical ones is the relatively invisible and silent operation of electricity. Broken mechanical systems are often diagnosed visually or with mechanical tools such as pressure gauges and dial indicators.

However, a defective engine sensor or broken wire in a harness is not so easily detected, and it can be a time-consuming operation to diagnose based on only symptoms and a multimeter. Self-monitoring or self-diagnostic capabilities are, therefore, built into electronic control systems to help technicians perform faster diagnostic checks and repairs. Electronic control modules can easily evaluate the voltage and current levels of circuits to which they are connected and determine whether the data makes sense and is in the correct operational range. These self-diagnostic capabilities are referred to as **onboard diagnostics (OBD)** systems.

All electronically controlled engines, powertrain components, and implement controls have built-in self-diagnostic capabilities. To communicate this data to an electronic service tool from even a single module requires the use of duplex or **bidirectional communications**, meaning two-way multiplex communication. As modules for transmissions, braking, and other electronic controls are added, network communication allowed these modules to communicate fault codes and data to a single diagnostic data link connector (DLC) (**FIGURE 19-10**).

Because a variety of modules can impact the machine's emissions, network communication needs to and does make it easy to identify specific faults using electronic service tools

connected to the DLC. For example, incorrect or missing machine speed data supplied by the transmission control module can interfere with correct injection timing and injection quantities, leading to excessive emission production. When a malfunction is detected, diagnostic information is stored in the machine's control module, which identifies the fault to assist in diagnosis and repair of the malfunction. The legislative standard developed by the International Society of Automotive Engineers (SAE) is referred to as heavy-duty onboard diagnostics (HD-OBD). This same legislation regulates the construction of a mandatory onboard network to access emission-related information. The OBD standard has many network-related requirements, all intended to reduce the cost and difficulties of repairing emission-related failures by independent repair facilities. Consequently, fault code reporting, the configuration of the DLC, communication language, and other network characteristics associated with emission control systems are standardized.

Ease of Connecting Electronically Controlled Accessories and Features

Machine accessories can be added at the factory or during after-market installation without any complex programming or equipment modification by using onboard networks. Connecting the device to the machine can occur automatically or by using service programming software. When a network-compatible accessory connects to a network, its presence is recognized and the network will provide access to information it needs to perform its job. This is much like plug-and-play hardware for personal computers. Remote power modules or other modules can be programmed to function per customized specifications, allowing machine builders to easily connect to the electrical system (**FIGURE 19-11**).

FIGURE 19-10 The 9-pin DLC enables service tool communication with the machine network.

FIGURE 19-11 Electronic controlled accessories that can be connected to the machines network.

SAFETY TIP

On J-1939 CAN networks, any module connected to the network must be certified as compatible. Non-compatible modules may work, but they can cause unusual, and even catastrophic, problems. For example, security systems or remote starters connected to the network or networked devices, such as door locks and starting/ignition circuits, can suddenly and unexpectedly cause a machine to stop operation. “Footprint errors” are also produced when incompatible devices are connected to the network. Any affected module must be completely reprogrammed. Even engine ECMs, which are reflashed or recalibrated with modified performance modifications, can send incorrect information over the network, adversely affecting machine operation.

TECHNICIAN TIP

The use of electronic service tools such as scanners, PCs, and other devices to communicate with modules connected to the machine network is critical to the diagnosis and repair of emission-related faults. Fault codes, communication language, and other features of the onboard network are standardized by EPA (Environmental Protection Agency) legislation to make it easier for technicians to repair a wide variety of machines with a minimum amount of electronic service tools. The right to repair aspects of the EPA legislation enabled aftermarket tool manufacturers—not just the OEMs—to supply service tools to communicate with the network.

Reduction in Number of Sensors

Sensor data can be shared across many devices connected into a network. This network feature eliminates duplication of sensors needed for a module. A simple example is the use of a machine speed sensor. This data is required in many places by various devices. The instrument gauge cluster, transmission, and engine all require machine speed data, as does the entertainment

system, which might lower or raise the radio volume depending on road speed. Using one electronic module to sense and process speed sensor data and then distribute the information over the network reduces the construction cost and associated wiring required to connect a sensor to each device that needs road speed data. Note also that the information-processing capabilities are distributed over many modules, which enhances the power of the total network. Instead of numerous modules performing the same task—such as processing speed data—only one module does it, which frees the processors in other ECMs to perform different work.

Other Network Outputs and Inputs

Multiplexed components on networks also include the following:

- instrument panel and gauge clusters
- odometers, now with digital LCD displays that can serve as a numeric fault code reader
- operator monitor
- cellular antenna system
- global positioning systems (GPS)

Multiplex switch packs permit dash switches to connect to the network with a twisted pair data bus. A variety of resistors and diodes within switch packs create a unique identifier for each switch, allowing them to be mapped to a unique function on the network (**FIGURE 19-12**).

This means that when accessories are installed, holes do not need to be cut into the dash, nor do new circuits need to be made. Outputs will originate from chassis or cab modules.

Power distribution modules incorporating inputs and power outputs with 20 amps or more of current-carrying capacity are useful programmable output devices. Modules containing **field effect transistors (FETs)**, which operate like a combined solid-state relay and a circuit breaker, also have virtual fusing for circuit protection. When current is applied to the gate, an FET can switch current flow like a regular switching transistor. However, a fourth leg or terminal on an FET allows monitoring of current levels through the FET. This means that if the programmed maximum current is exceeded, the current flow will switch off the FET.

Controlled Area Networks

K19004, S19003, S19004

The term **controlled area networks (CAN)** describes a distributed network control system. This means no single central control module is used. Instead, each module or node on the network has processing capabilities that can initiate electrical control for faster response and also synchronize their operation with other network modules. Therefore, each module on the network has memorized the rules of what it has to do and what the rules are for doing it. Because the network has no central control, the connected components will still operate in the event that parts of it are severed.

CANs are the most widely used type of network for integrating powertrain operation of all the latest machines. These

FIGURE 19-12 Programmable switch packs enable the customization of switch functions.

networks are often integrated in local area networks (LANs), which are machines using multiple types of networks on a single chassis, such as optical or other specialized proprietary networks connecting manufacturer-specific equipment. Because there is no central control module coordinating communication or controlling network devices, each network module has built-in processor capabilities to process input and output data while simultaneously receiving and transmitting data to the network. A built-in clock and transceiver in each CAN module helps synchronize multiplex communication between modules, so each takes an appropriate turn using the data bus to send and receive messages.

Other processing functions built into every CAN module allow it to interpret other network communication data and control the messages it sends to the data bus. This degree of sophistication makes CAN nodes more expensive to build. Other onboard networks are built to reduce costs and increase CAN speed.

J-1939 Versus J-1708/1587

Two different types of CANs used by mobile off-road equipment are the SAE network standards J-1939 and J-1587/1708. The J-1587/1708 CAN is identified by the six-pin DLC. It is an older network that transmits data at the relatively slow speed of 9,600 bits/second. J-1708 refers to the standards for the physical layer or just specifications for data bus construction. J-1939 has standardized fault codes and uses an SAE set of rules to govern the communication over the J-1708 physical network. The J-1708 data bus

- contains two twisted wires using 18-AWG that are color-coded orange and green
- links all electronic modules on the machine

- communicates at 9,600 bits per second (bps)
- transmits at a maximum distance of 131 feet (40 meters)
- connects up to 20 modules or nodes.

Beginning in 2001, J-1939 began replacing the J-1708 standard for data bus. The J-1939

- uses two twisted wires of 18 AWG that are color-coded yellow and green
- connects only modules that are compatible with the J-1939 standard
- requires terminating resistors
- communicates at 256,000 bps
- transmits at a maximum distance of 131 feet (40 meters)
- connects up to 30 modules or nodes
- stub connections to the twisted wire backbone are limited to 3 feet (1 meter) in length.

J-1939 defines not only the construction of the data bus but also all features and characteristics of the network. Contrasted to J-1957/1708, J-1939 is like high-speed Internet access compared to dial-up in terms of the amount of data carried per second. J-1587 and J-1939 use serial data communication protocols, which have similar characteristics but which differ in relation to rules about such things as message structure, transmission speed, connectivity hardware configuration, and diagnostic fault codes.

Serial Communication

Serial communication is like electronic Morse code. Instead of dots and dashes, however, 0s and 1s are transmitted in a series, one after another, using voltage pulses. As there is only one

FIGURE 19-13 A serial data waveform from a J-1939 network.

path, data is transmitted one bit at a time, one bit after another, or in series (FIGURE 19-13).

A positive voltage of anywhere between 2 and 8 volts in comparison to a pulse of lower voltage would represent a 1. No voltage—or voltage close to 0 and no higher than +1.5 volts—represents a 0. Voltage on the paired wires is a mirror opposite to produce a sharp, crisp differential voltage that is easily understood by the modules (FIGURE 19-14).

Using differential voltage and twisting the wires minimize electromagnetic interference (EMI) in the wires, also called electrical noise, in wiring carrying serial data.

J-1939 communications have two wires: one wire, called CAN-hi, has a more positive voltage than the other, called CAN-lo. Each wire will have a mirror opposite charge of the other when communication takes place.

Twisted Wire Pair Data Buses

Wires are twisted to minimize electromagnetic interference caused by magnetic fields and radio waves (FIGURE 19-15).

FIGURE 19-14 Differential voltage, or differential mode transmission, of serial data ensures that a clear, crisp electrical signal is transmitted over the data bus.

FIGURE 19-15 EMI sources that can affect the data bus. Differential voltage transmission minimizes signal interference.

For example, magnetic fields from starters, electric motors, injectors, or radio signals from CB (citizens band) radios can penetrate the wires and induce voltage. Distortions to voltage signals can garble or change network messages. A cancelation effect is achieved using differential voltage signals, as the two wires carry equal and opposite voltage polarity. When the signal reaches its destination, network modules detect the voltage difference between the two wires to determine whether the signal is a 1 or 0. This type of interpretation of the signal is known as **differential mode transmission**, and it provides a crisp, clear waveform. Note that J-1587/1708 networks reference the CAN voltage from ground and that the differential voltage measured between the two CAN wires is slightly higher than it is in J-1939 signals.

EMI introduced into the wires tends to affect both wires equally when wires are twisted together five turns per inch or

two turns per centimeter. The low-voltage signal of the CAN data bus is even more susceptible to EMI due to the transmission speed of 256 kbps to 800 kbps. Not only are wires twisted together to resist induction of current, but on earlier machines, they were also covered in a metal foil to absorb EMI signals. A third wire attached to the foil drains away induced current flow in the foil to ground. This is similar to the use of the braided shielding wire used on TV cable. With the TV cable, the inner wire carries the signal and the outer braided wire shields the inner cable from interference that would produce a static-filled, distorted picture.

To further minimize signal distortion, at each end of the J-1939 CANbus, there is a 120-ohm resistor that extinguishes multiplex voltage signals to prevent their reflection through the data bus (**FIGURE 19-16**).

Similar to a lightbulb, which converts current to heat and light, resistors absorb signals to increase transmission speed on the data bus. The J-1939 data bus also minimizes distortion of data caused by EMI interference. On a CAN, the CAN-H (high) wire is yellow and carries positive voltage (CAN+). The green wire, CAN-L (low) (CAN-), is negative. Signals could be transmitted over a single wire; if one of the wires were broken or grounded out, using the voltage-differential mode of transmission would provide a better signal quality capable of very high rates of data transmission.

CAN+ and CAN- wires provide 60 ohms of resistance. Disconnecting either of the terminating resistors causes the bus resistance to rise to 120 ohms. If the resistance of the data link is 120 ohms, then either there is an open circuit somewhere or a terminating resistor is missing. Pinched, cut, or shorted data bus wires will extinguish any network communication. The outer foil should have continuity with chassis ground and none to either of the twisted wire pair. Repairs to the bus need to be performed according to prescribed manufacturer procedures. Field experience has demonstrated that if only one J-1939 terminating resistor is missing, the network or machine will likely not have any operational problems. However, if both terminating resistors are missing, no communication is possible (**FIGURE 19-17**).

FIGURE 19-16 A terminating resistor for a J-1939 network.

FIGURE 19-17 Waveforms when resistors are missing from a J-1939 data bus. **A.** Two resistors. **B.** One missing resistor. **C.** No resistors (all resistors missing).

To measure the resistance of terminating resistors, follow the steps in **SKILL DRILL 19-1**. Note that you should perform this test only after disconnecting the batteries.

► TECHNICIAN TIP

Only one connection to ground should be made on the J-1939 drain wire. If more than one connection is made to ground, the outer shielding can become a circuit pathway. This will in turn intensify EMI interference if electrical current moves through the drain conductor.

Network Messages

Using CAN networks is like shouting a message in a well-ordered room crowded with people. Everyone can hear the message, but not everyone will respond or is permitted to speak at once because of message rules. Using the CAN protocols, however, is not as potentially confusing as a room full of shouting people. Instead of people, modules are communicating with one another operating under a strictly defined set of rules to

SKILL DRILL 19-1 Measuring Resistance of Terminating Resistors

1. With the ignition off, disconnect the batteries.
2. Connect the leads of a digital multimeter to pins C and D of the 9-pin diagnostic connector.
3. Set the multimeter to read in ohms.
4. Measure and record the resistance. Normal resistance should be 60 ohms; 120 ohms indicates one missing resistor; 45 ohms indicates an extra resistor. With both resistors removed, there should be a high resistance of more than 10k ohms, but not infinite resistance.

control communication. To accomplish this, data carried on the CANbus has four distinct message formats:

1. Dataframe—its message format is something like this:
 - a. “Hello, everyone. Here’s some information labeled X. I hope it’s useful!”
2. Remote frame—its message format is something like this:
 - a. “Hello, everyone. Can somebody please send the information labeled Y?”
3. Error frame—its message format is something like this:
 - a. (Everyone out loud) “Can you repeat that?” This message is sent by modules that do not understand a message if the information is garbled or is not sent according to rules.
4. Overload frame—its message format is something like this:
 - a. “I’m a very busy at the moment with the GPS module, sending something more important. Could you please wait another moment?”

Using these message formats that determine which module is transmitting or receiving data, problems with message transmission are eliminated while communicating huge quantities of information.

Message Format

Messages sent and received over the network are constructed in frames and have a maximum message length of 130 bits. This maximum message length is, by digital data standards, short. A short message ensures the wait time for each message is as brief as possible. Each of the above message types is further divided into sections. Examples of frame sets included in the above message include a start frame, which indicates the start

of the message. Another frame identifies the type of message, such as whether it is from the engine or transmission, and how important or what priority it has. For example, slow-changing data, such as coolant temperature, would have less priority or urgency than, say, a wheel lock-up event reported by the ABS (antilock brake system). Another frame within the message provides the actual data that is of interest to the modules, such as machine speed or whether the air conditioning is on or off. Finally, a couple of other frames are used to indicate the end of a message (FIGURE 19-18).

All modules acknowledge the receipt of information transmitted from a specific module by indicating there were no corrupted messages. This is like ending a telephone call with the message, “Did you hear what I said? Everyone says OK and goodbye.”

No centralized special software controls the network communication. Operating instructions are imbedded in the memory chips used by the CAN module connected to the network. Manufacturers supplying devices connected to the network must ensure the devices are constructed to design specifications that make them network compatible. This enables the use of the plug-and-play feature of the network.

Data Bus Arbitration

Deciding which messages have priority to transmit over the network to prevent data collision between positive and negative signals is called **arbitration**. As soon as the data bus is free (i.e., the telephone line is not busy), each node or module can begin transmitting information. If two or more modules start transmitting at once, the message format decides which message has access to the data bus. For example, a wheel lock-up event or a traction control module message indicating excessive wheel slip will have priority on the data bus to supply information to the engine ECM and reduce power output. Modules with

FIGURE 19-18 Construction of a J-1939 network message. Message information also includes whether the data is a fault code or simply system information.

lower priority messages automatically switch from transmitting to receiving and repeat their transmission as soon as the bus is free again.

Gateways—Joining Multiple Networks Together

Today, multiple networks exist on most machines. Rarely does contemporary equipment use only a single CAN for powertrain- and emission-related functions. The reason for multiple networks is primarily cost. Modules used on CANs have far more sophisticated microprocessors, software, and related electronics to operate on these networks with the complexity of communication protocols characteristic of CAN. Manufacturers can produce less-expensive, less-sophisticated modules, nodes, or devices for centrally controlled networks than they can for distributed CANs. Furthermore, manufacturers will often use their own in-house or proprietary networks for controlling unique OEM electrical devices on the network.

Many manufacturers often use **ladder logic**, a software-based control system that replicates relay-based electrical system operation. Where wiring diagrams once depicted battery current flow through electrical connections and devices and showed relays switched open or closed, ladder

logic shows rules for software logic to control devices. For example, to operate a starting motor, the electrical system control software would need to confirm that a specific set of conditions is met by verifying a set of true/false statements, such as the following set:

- The ignition switch is in the start position = true/false.
- The transmission is in neutral = true/false.
- Battery voltage is above 10.6-volts = true/false.
- The hydraulic lockout is on = true/false.

Wireless Network Communication

Cell phone and Bluetooth technology are two additional methods of network communication that use wireless network interface. A Bluetooth-equipped phone, when recognized by the network, will turn down the volume of a radio and even transmit the call to the entertainment system or a headset for hands-free communication. Similarly, many aftermarket consumer devices such as navigation systems, entertainment devices, security alarms, media players, and pagers can be connected to the machine network with a touch of a button, or even with voice commands. Bluetooth communication technology is used to connect these devices to the networks and supply information for them to operate properly or to enhance functionality. Cell phone technology is also used

FIGURE 19-19 Telematics solution for remote monitoring.

in system interface. **FIGURE 19-19** shows a telematics technology that continuously transmits network information from a variety of modules to a central dispatch, where the data is monitored.

The machine network modules provide many features:

- remote machine diagnostics
- remote door unlocking
- locating lost or stolen machines
- remote ignition lock-out if the machine is stolen
- remote monitoring of payload data such as: tons per hour, total tonnage, overload warnings and cycle times
- the real-time positions, speed, status, and activities of a machine.

Bluetooth Technology

Bluetooth is a short-range wireless technology that can automatically connect a device to a network. Cell phones are a common application for Bluetooth technology, used to connect a phone with the audio system using the onboard network. Many machines today are equipped or retrofitted with a wireless communication module connected to the data bus of the onboard machine network to communicate with Bluetooth and other radio devices, such as key fobs and cell networks. Instead of using wires to communicate with the network, Bluetooth devices (such as cell phones) use radio

frequencies. Communication from the cell phone to network is also multiplexed over a wide number of shifting radio frequencies. Frequency shifting happens much like changing the radio station several times every second, with both the network and the cell phone simultaneously exchanging data on different frequencies. To start a connection, the Bluetooth device will send a signal on a predefined radio frequency, telling the wireless module or node that it wants to communicate. The module, in turn, will send back a mathematical formula to the Bluetooth device telling it which frequencies to use and when. Communication can then begin between the wireless **network node** and the Bluetooth device. The communication formula that determines which radio frequencies to use and when to use them is constantly updated during the interaction.

► Diagnosing Network Communication Problems

K19005, S19005, S19006

Problems on networks commonly originate from the following causes:

- shorted or defective CAN modules
- shorts to ground, power or CAN-H and CAN-L wires
- missing terminating resistors
- additional terminating resistors.

When network problems are present, the symptoms can vary widely from machine to machine, depending on the fault and manufacturer. The machine may not start at all or may accelerate slowly (if it accelerates at all), the transmission may not shift properly, lights may be out, etc. (**FIGURE 19-20**).

Disconnecting modules one by one can help identify a module that is shorting out the CANbus. But the best diagnostic routine to identify a network problem is to perform resistance and voltage checks of the CANbus at the DLC. The HD-OBD system monitors the CANbus voltage and will report network faults if the voltage measurements are not correct or if there is a problem with the data. The failure of a service tool to communicate with the DLC requires a check of the voltage on the CAN pins, which should be a minimum of 1 volt. After disconnecting the batteries to remove all machine power, resistance checks of the terminating resistors can be performed. Too many or too few resistors will give an incorrect resistance reading. The proper resistance should be close to 60 ohms.

To perform a DLC voltage check, follow the steps in **SKILL DRILL 19-2**. This test checks whether enough voltage is available on the DLC CAN lines to transmit data. And to check for shorts in the CAN, follow the guidelines in **SKILL DRILL 19-3**. Again, perform this test only after disconnecting the batteries.

FIGURE 19-20 CANbus defects.

SKILL DRILL 19-2 Performing a DLC Voltage Check

1. Set the digital multimeter (DMM) to read in ohms.
2. With the ignition on, connect the leads of a DMM to pins C and D of the 9-pin diagnostic connector.
3. Measure and record the voltage. The voltage should be more than 1 volt. If not, there is no network communication taking place.

SKILL DRILL 19-3 Checking for Shorts in the CAN

1. With the ignition off, disconnect the batteries.
2. Connect one lead of a DMM to pin C of the 9-pin diagnostic connector.
3. Connect the multimeter lead to chassis ground.
4. Set the multimeter to read in ohms.
5. Measure and record the resistance.

6. Connect one lead of a DMM to pin D of the 9-pin diagnostic connector.
7. Connect the other multimeter lead to chassis ground.
8. Measure and record the resistance. The resistance between chassis ground and pin C and D should be infinite or out of limit.

Wrap-Up

Ready for Review

- ▶ Onboard machine networks are formed by connecting machine electronic control modules to one another to communicate and exchange information.
- ▶ Communication takes place between all the modules and devices connected to the network through the use of an electrical signal-processing strategy called multiplexing.
- ▶ Onboard networks can be categorized by typology, their physical layer, their network protocol, or by whether they have centralized or distributed control.
- ▶ Networks are formed based on organizational priorities, with modules grouped by area or function, such as those involved in engine, transmission, implement, climate control, instrumentation, entertainment devices, or body electrical control.
- ▶ The type of multiplexing used in onboard networks works by dividing the time available to each network module or device to transmit and listen to information. Only one module is allowed to talk, and all other modules must listen until it is their turn to talk.
- ▶ Advantages of multiplexing include the software control of the electrical system, enabling onboard diagnostics, ease of connecting electronically controlled accessories and features, and a reduction in the number of sensors.
- ▶ Controlled area networks are the most widely used type of network for integrating the machine operation of all the latest equipment.
- ▶ Two different types of CANs used by mobile off-road equipment are the SAE network standards of J-1939 and J-1587/1708.
- ▶ In serial communication, one wire, called CAN-hi, has a more positive voltage than the other, called CAN-lo. Each wire will have a mirror opposite charge of the other when communication takes place.
- ▶ Wires are twisted to minimize electromagnetic interference caused by magnetic fields and radio waves.

To further minimize signal distortion, at each end of the J-1939 CANbus there is a 120-ohm resistor that extinguishes multiplex voltage signals to prevent their reflection through the data bus.

- ▶ Network signals are distorted and slowed if terminating resistors are missing or defective.
- ▶ Data carried on the CANbus has four distinct message formats: data frame, remote frame, error frame, and overload frame. Messages sent and received over the network are constructed in frames with a maximum message length of 130 bits.
- ▶ Messages are prioritized to prevent data collision between positive and negative signals canceling one another.
- ▶ Cell phone and Bluetooth technology are two levels of network communication that use a wireless network interface.
- ▶ Disconnecting modules one by one can help identify a module that is shorting out the CANbus, but the best diagnostic routine to identify a network problem is to perform resistance and voltage checks of the CANbus at the DLC.

Key Terms

arbitration The process of deciding which messages have priority to transmit over the network to prevent data collision between positive and negative signals canceling one another.

bidirectional communication Two-way multiplex communication.

Bluetooth A short-range wireless technology that can automatically connect a device to a network.

controlled area networks (CAN) A distributed network control system in which no single central control module is used.

data bus The typology that forms the communication pathway of modules in a network.

differential mode transmission A situation in which network modules detect the voltage difference between two wires to determine if a signal is a 1 or a 0.

field effect transistor (FET) A unipolar transistor that uses an electric field to control the conductivity of a semiconductor material.

gateway module A module that translates communication between different networks that operate with the use of different protocols or speeds.

ladder logic The designed-in logic of a circuit that determines what activates a specific circuit.

multiplexing Transmission of more than one electrical signal or message takes place over a single wire or pair of wires.

network node A point on a network.

onboard diagnostics (OBD) Self-diagnostic capabilities of electronic control modules that allow them to evaluate voltage and current levels of circuits to which they are connected and determine whether data is in the correct operational range.

serial communication Communication using 0s and 1s to transmit data in a series, one bit after another in sequence.

serial data Pieces of data sent by the master module.

time division multiplexing (TDM) A type of multiplexing used in onboard networks and that works by dividing the time available to each network module or device.

typology The manner in which modules are connected to one another.

Review Questions

1. What terminals of the 9-pin diagnostic connector are connected to a digital multimeter (DMM) to check the resistance of the terminating resistors used for the CANbus?
 - a. A and B
 - b. 14 and 16
 - c. C and D
 - d. 3 and 4
2. Communication between all the modules and devices in a machine that is connected to a network that uses an electrical signal-processing strategy is called which of these?
 - a. Networking
 - b. Multiplexing
 - c. Communication
 - d. Linking
3. The rules or standards used to communicate over the networks are called _____.
 - a. network protocol
 - b. typology
 - c. physical protocol
 - d. CAN (controller area network)
4. Electronic control modules can easily evaluate the voltage and current levels of circuits to which they are connected and determine whether the data makes sense and is in the correct operational range. These self-diagnostic capabilities are referred to as which of these?
 - a. CAN (controller area network)
 - b. OBD (onboard diagnostics)
 - c. network protocol
 - d. typology
5. All networks have in common the concepts of interconnected modules. The use of _____ enables digital communication between each module and time division multiplexing as a communication strategy.
 - a. scan tools
 - b. multiplexing
 - c. serial data
 - d. parallel data
6. When paired together and connected in parallel to all modules in the network, the typology forming the communication pathway is called a _____.
 - a. bus
 - b. network
 - c. system
 - d. circuit

7. What requires the modules and other devices to take turns, sharing the data bus communication pathway?
 - a. Data sharing
 - b. Time division multiplexing
 - c. A network
 - d. A circuit
8. When using networks, electrical system complexity is absorbed by the _____ instead of a huge array of hard-wired components and circuit boards.
 - a. computer
 - b. controller
 - c. network
 - d. software
9. All electronically controlled engines and powertrain components have built-in self-diagnostic capabilities. To communicate this data to an electronic service tool from even a single module requires the use of _____.
 - a. bidirectional communications
 - b. a factory scan tool
 - c. direct communication
 - d. a personal computer
10. Self-diagnostic capabilities are referred to as which of these?
 - a. Diagnostic circuit check
 - b. Off-board diagnostics
 - c. Onboard diagnostics (OBD)
 - d. Diagnostic control
- c. Both Technician A and Technician B
- d. Neither Technician A nor Technician B
4. Two technicians are discussing machine serial data communication. Technician A says that the advantages of multiplexing include software control of the electrical system, enabling onboard diagnostics, the ease of connecting electronically controlled accessories and features, and a reduction in the number of sensors. Technician B says that controlled area networks are the most widely used type of network for integrating powertrain operation of all the latest machines. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says that in serial communication, one wire, called CAN-H, has a more negative voltage than the other, which is CAN-L. Technician B says that each wire will have a mirror opposite charge of the other when communication takes place. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
6. Two technicians are discussing machine serial data communication and networks. Technician A says that data carried on the CANbus has four distinct message formats: data frame, remote frame, error frame, and overload frame. Technician B says that cell phone and Bluetooth technology are two levels of customization realized using a wireless network interface. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
7. Technician A says that broken mechanical systems are often diagnosed visually or with mechanical tools such as pressure gauges and dial indicators. Technician B says that self-monitoring or self-diagnostic capabilities are, therefore, built into electronic control systems to help technicians perform faster. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says that wires are twisted to minimize electromagnetic interference caused by magnetic fields and radio waves. Technician B says that network signals will never be distorted and slowed if terminating resistors are missing or defective. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

ASE Technician A/Technician B Style Questions

1. Two technicians are discussing checking the voltage at the 9-pin diagnostic connector or datalink connector (DLC). Technician A says that voltage is checked with the ignition on at terminals C and D. Technician B says that the voltage at terminals C and D should be at least 12.6 volts. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. When inspecting for shorts on the CANbus, Technician A says that neither CAN-H nor CAN-L should have continuity with chassis ground. Technician B says that only the CAN-L should have continuity with ground. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says that to check for fault codes, only a scanner or personal computer connected to the data link connector can retrieve codes. Technician B says that fault codes could also be retrieved from an instrument cluster display. Who is correct?
 - a. Technician A
 - b. Technician B

9. Two technicians are describing the use of electronic service tools. Technician A says that all fault codes, communication language, and other features of the onboard network are standardized by EPA legislation. Technician B says that only the equipment manufacturer's specific scan tool or software can read the legislated fault codes. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
10. Technician A says that disconnecting modules one by one can help identify a module that is shorting out the CANbus. Technician B says that the best diagnostic routine to identify a network problem is to perform resistance and voltage checks of the CANbus at the DLC. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

CHAPTER 20

Onboard Diagnostic Systems

Knowledge Objectives

After reading this chapter, you will be able to:

- **K20001** Identify and describe the principles of onboard diagnostic (OBD) systems.
- **K20002** Identify and describe features of onboard diagnostic and off-board diagnostic strategies.

Skills Objectives

There are no skills objectives for this chapter.

► Introduction

Technicians servicing today's machines will be just as likely to use a computer as a screw driver to perform repairs. Electronic systems using microprocessors control cab, engine, implements, and drivetrain systems and provide operational capabilities far exceeding any mechanical system—and with greater precision, efficiency, and reliability.

Although electronics offer many advantages over mechanical controls, a new challenge is to quickly identify and repair any failure in systems that operate with increasing invisibility by using electronic signals and software-based operating systems. To prevent a problem as simple as a broken wire from requiring a huge number of labor hours to identify and repair, electronic systems have self-diagnostic capabilities. These self-diagnostic capabilities extend to the emission systems, which also must operate flawlessly in order for the normal service life of the machine to maintain almost undetectable emission levels from the latest engines.

► Fundamentals of Onboard Diagnostics

K20001

The dominance of electronics makes skill development related to servicing electronic control technology one of the most important priorities for successful technicians. Understanding the operating principles of electronic control systems is foundational for choosing diagnostic strategies, using service tools effectively, and making sound repair recommendations. Nowhere are these skills more important than in comprehending and troubleshooting the operation of the OBD system. This unique system is responsible for maintaining a machine's compliance with emission standards. The comprehensive monitoring of the machine performed by the OBD system means electronic-related faults requiring service will be identified by the OBD system.

Development of Onboard Diagnostics

The term OBD has two meanings for the technician. The simplest, most familiar definition is the diagnostic function of

electronic control systems to identify or self-diagnose system faults and report fault codes. The second meaning is the legislated standards for maximum machine emissions levels. The legislation also establishes requirements for maintaining the lowest machine emissions and alerting the operator if any fault occurs that could potentially cause emissions to increase above specific thresholds or levels.

Onboard Diagnostics

Emission standards established for off-road diesels, beginning in late 1994, have required a level of precision for engine control that is possible only through the extensive use of electronics. Electrical devices now perform the work once done by fuel system camshafts, levers, springs, flyweights, and other assorted mechanical devices. Because of the invisible nature of electronic signals and the operation of microprocessors executing thousands of lines of software code, many hours would be spent to identify simple problems, such as a broken wire or faulty sensor, if these systems did not have self-diagnostic capabilities. This self-diagnostic capability, referred to as the OBD system, was originally developed by manufacturers to enable technicians to service electronic controls. When a malfunction is detected, diagnostic information is stored for retrieval by a technician to assist in the diagnosis and repair of the malfunction (**FIGURE 20-1**).

FIGURE 20-1 Use OBD to identify and report fault codes.

You Are the Mobile Heavy Equipment Technician

You are at a customer's yard to diagnose a problem with a brand-new wheel loader. The starter cranks, but the engine will not start. You perform typical visual inspections of the machine, examine the fuel system and engine wiring harnesses, and check for leaks. Nothing seems amiss, but you realize that the check engine light stays on. It would not take long to change the fuel filters out, but if they are not the problem, warranty would not pay for them. You know that an engine position sensor and its circuit could cause this problem, so consider the following:

1. What two procedures, other than using original equipment manufacturer (OEM) or other diagnostic software, can you use to retrieve fault codes?
2. Explain why the check engine lamp stays on.
3. Are SAE J-1939 fault codes retrievable from this machine without OEM software? Explain your answer.

► Self-Diagnostic Capabilities and Approaches

K20002

Electronic systems do not have many moving parts to wear out, but the systems can be complex. When something goes wrong with a component or circuit, identifying the problem without some built-in self-monitoring and self-diagnostic capabilities can be extremely time-consuming and difficult. Consider what steps would be needed to identify a problem as simple as a bent pin on a control module or a broken or worn wire on today's machines. Many hours, if not days, would be needed to trace every individual circuit while performing voltage and resistance checks. With built-in self-monitoring functions, electrical systems can check circuits and electrical devices, evaluate the accuracy of sensor data, and identify problems as they occur. The system records and reports when, where, and how faults occurred, enabling diagnostics on electronically controlled machine systems to be performed easily, often with fewer tools and in less time than on mechanical systems.

The system can take one of two self-diagnostic approaches to identifying faults. The system can either use traditional self-diagnostic strategies or use a model-based approach.

Traditional self-diagnostic strategies focus on specific areas of machine control, such as the engine, transmission, and implement control. In machines where only a few control modules are used and communicate with one another, out-of-range-type fault codes and off-board fault isolation methods are adequate.

System self-diagnostic checks are generally performed by the self-monitoring system by range checking sensors or circuit data. For example, if the signal voltage produced by a coolant temperature sensor exceeds the limits of normal operation, the system will generate an out-of-range electrical fault code (FIGURE 20-2).

A problem with allowing the system to generate fault codes based on simply range checking a sensor or circuit for correct electrical values is that the code will point to a general circuit problem that requires off-board pinpoint testing to determine whether it is the sensor, wiring, or even a disconnected or missing sensor. As system complexity evolved, the technician performed off-board diagnostics after the onboard system identified a fault. Using flow charts for a specific diagnostic code (e.g., troubleshooting diagnostic trees) in more sophisticated electronic control systems became more time-consuming and sometimes ineffective, resulting in a high number of “no fault found responses.”

Manufacturers have also discovered incorrect component replacements and increased warranty costs are associated with a high reliance on off-board diagnostic testing by technicians even using the appropriate service literature. Furthermore, even with a fault code, from a sensor as simple as the coolant temperature, it could be a cooling system problem and not a sensor fault. The cooling system operation could be out of normal operating range and yet a coolant temperature sensor fault code is generated, but it's the system and not the sensor operating incorrectly.

FIGURE 20-2 Older OBD systems monitored electrical circuits and reported out-of-range voltage signals as electrical faults. Newer systems monitor overall system behavior, comparing it to models of expected behavior; in addition to out-of-range circuit faults.

To correct the shortcomings of range-check-only diagnostic systems, *model-based diagnostics* compare system and component behaviors to expected patterns of operation. In addition to fault detection and isolation, the model-based approach also analyzes and categorizes the fault by using advanced algorithms. System problems are generally identified without interfering with system operation by substituting suspected data from a sensor or device with a backup or default data set.

Diagnostic Definitions

A variety of terms are used to categorize abnormal system operation.

1. **Fault:** A fault is a deviation of at least one characteristic property of the system from its standard behavior. Low battery voltage, excessive oil pressure, and a missing sensor input are examples of faults. Depending on how quickly a fault occurs and whether it persists, faults are classified in four categories:
 - **Active:** This type of fault is currently taking place and is uninterrupted in action. Sudden component or circuit problems are generally active faults. An illuminated malfunction indicator light (MIL) or check engine light (CEL) indicates an **active fault**.
 - **Historical:** This type of fault, which is also called inactive or logged, took place at one time but was corrected and is no longer active. A sensor that was temporarily disconnected is an example of a **historical fault**. Amber check engine lights can also indicate the presence of historical faults.

- **Intermittent:** This type of fault is not ongoing and can be both active and historical. Loose connectors or poor pin contact can cause an **intermittent fault**.
 - **Incipient:** This type of fault is the result of system or component deterioration. An exhaust particulate filter filling with ash is an example of an **incipient fault**.
2. **Failure:** This refers to a fault that permanently interrupts a system's ability to perform a required function under specified operating conditions. Open or shorted circuits, cylinder misfires, or a seized variable geometry turbocharger (VGT) actuator are examples of failures. Failures produce active fault codes.
 3. **Disturbance:** This is an unknown and uncontrolled input acting on the system. Electromagnetic interference, loss of mass, fluid or gas leakage from a hydraulic or pneumatic system, or excessive mechanical friction are examples of unknown or uncontrolled disturbances affecting system inputs. Low coolant level in a system without a level sensor could be an example of a disturbance.
 4. **Fault detection:** This is a diagnostic strategy to determine whether faults are present in the system. An electronic control module will continuously check for voltage drops for all input and output circuits. Emissions system monitors

are typical examples of a fault detection strategy used to evaluate a system's operation based on a model of expected behavior compared with actual performance of individual components or systems.

5. **Fault isolation:** This involves determining the location of the fault. Fault isolation is best accomplished using a diagnostic fault tree supplied by the manufacturer (**FIGURE 20-3**). Examples of fault isolation include pinpoint electrical testing using a voltmeter, an ohmmeter, or commanding actuator tests.
6. **Fault accommodation:** This happens when a fault is detected. Fault accommodation, which is also known as an adaptive strategy, reconfigures the system operation or substitutes suspect data with default data to maintain normal system functionality even with the fault. This strategy is also called fault healing. One example is a newer engine that continues to run after it has lost data from a defective crank or the cam position sensor. The control modules will substitute a value derived by using data from the other sensor to keep the engine running, although not as well. For example, defective mass air flow sensor data could be replaced by intake manifold pressure and temperature data.

FIGURE 20-3 Use diagnostic fault code trees after retrieving a fault code, in order to complete appropriate checks. When multiple codes are set, observe code priority.

► TECHNICIAN TIP

Adding auxiliary heaters for passenger compartments can cause the cooling system monitor to indicate a fault. Taking heat out of the cooling system during engine warm up will delay the time to warm up, which will illuminate the MIL.

Maintaining OBD

Maintaining the OBD system is critical in order to identify and address machine system deterioration and remedy failures. Technicians must understand how to use off-board diagnostics and interpret readiness and diagnostic trouble codes in order to diagnose a system properly and make appropriate repairs.

Off-Board Diagnostics

When electrical faults or system problems occur in machine control systems, electronic control modules log **diagnostic trouble codes (DTCs)** in the system memory, which are read through an instrument display cluster, also called a **blink code**, or retrieved by a scanner or personal computer connected to the machine DLC. OBD is the self-diagnostic checks by the control modules that measure circuit voltages, resistances, rationality, and other variables. More sophisticated OBD systems monitor system behavior to detect smaller faults faster. **Off-board diagnostics** and repair occur when the technician retrieves codes and machine data as a starting point to diagnose system problems. During off-board diagnostics, the technician may monitor system operation, perform actuator tests, pinpoint electrical tests, and inspect components. Remotely assisted diagnostics using **telematics** is also a type of off-board diagnostics. Telematics is a branch of information technology that uses specialized applications for the long-distance transmission of information to and from a machine (**FIGURE 20-4**).

Readiness Code

Depending on the OEM, some provision is made to validate whether a component or emissions system generating a DTC

has been repaired or corrected. After a repair has been made, operating the machine under conditions that cause an emissions system monitor to self-check validates whether a successful repair has been completed. An OBD service tool displays a readiness code indicating that a monitor has completed its functionality test and that no fault was found. Each monitor requires a unique set of machine operating conditions to be met before it can properly run and evaluate the performance of an emissions system.

When an OBD readiness code validates the system that has been repaired, no other fault codes associated with the system should be active. However, a message such as “system not ready,” “monitor incomplete,” or “monitor not run” is displayed if the repair is not successful or if the emissions system has not met the conditions needed to enable the monitor to run.

► TECHNICIAN TIP

After repairing a fault associated with the engine or power train, the codes should be cleared and the machine tested, which involves operating the machine under the conditions necessary for a monitor to run (i.e., operating temperature). Recheck the machine for codes after the test, before returning the machine to the customer. The monitor associated with the repaired fault should indicate it has “run” or is “ready.”

Emissions System Deterioration

The OBD is primarily an emissions-driven diagnostic system. For diesel engines, the threshold for alerting the operator and setting a fault code generally occurs any time a condition is sensed that could cause noxious emissions to exceed the legislated federal test protocol (FTP) emissions standards 1.5 times. Higher thresholds are used for aftertreatment systems, with progressively lower threshold standards for the latest machine models. While malfunctions in the engine cause excessive emissions, problems with other machine systems can also cause the machine to exceed the threshold for emissions. Adaptive strategies can compensate for system deterioration. For example, wastegated turbochargers

FIGURE 20-4 Performing off-board diagnostics involves isolating a fault based on fault code information.

have metal springs in their actuators. Heat and time will weaken the springs, so closed-loop feedback between the wastegate and the boost pressure sensor compensate for system deterioration. Common rail injectors are regularly checked using zero-fuel adaptation, which automatically updates the calibration file during engine deceleration.

Diagnostic Trouble Codes

The OBD system sets three types of codes: A, B, and C. Type A DTCs are the most critical emissions-related faults and will illuminate the MIL with only one occurrence. If a Type A code is set, the OBD can store it several ways. Type A codes are generally stored in the engine control module (ECM) historical memory. To help the technician diagnose the problem, the code has a failure record associated with it, such as a time and date stamp of when the last failure occurred, whether the code occurred since the last code clearing event, or whether the failure has occurred during the current ignition cycle. Furthermore, Type A codes have freeze-frame data, which is a record of all other sensor data occurring when the fault was detected.

Type B codes are emissions-causing faults that are less serious than Type A faults and must occur at least once on two consecutive trips before the MIL will illuminate. The MIL will also go out if a Type A or Type B DTC problem does not reoccur after a predetermined number of warm up/cool down cycle (e.g., 3–5 warm up/cool down cycle—which varies by OEM).

Type C DTCs are non-emissions-related codes, or enhanced codes. Enhanced codes also cover non-emissions-related failures that occur outside the engine control system.

Freeze-Frame Data

The freeze-frame data the ECM stores will provide a snapshot of the engine operating conditions present at the time the malfunction was detected. This information should be stored when a pending DTC is set. If the pending DTC matures to a MIL-on DTC, the manufacturer can choose to update or retain the freeze-frame data stored in conjunction with the pending DTC. Likewise, any freeze-frame data

stored in conjunction with a pending or MIL-on DTC should be erased upon erasure of the DTC.

OBD Emissions Codes

The OBD executive is an element in the emissions system's operational strategy that manages the DTCs and operating modes for all diagnostic tests related to emissions systems. It can be referred to as the "traffic cop" of the diagnostic system, managing DTC storage and MIL illumination. Note that the HD-OBD MIL light is yellow, unlike the light-duty OBD-II system, which is red.

Control modules that contribute to maintaining emissions compliance must be connected to the controller area network bus (CANbus) using SAE J-1939 standards for communication and network operation (FIGURE 20-5, FIGURE 20-6).

CANbus modules performing emissions diagnostics will include the following types:

- engine ECM
- machine electronic control unit
- aftertreatment control module

FIGURE 20-5 HD-OBD data can be accessed from the CANbus through the data link connector.

FIGURE 20-6 A CANbus connects machine modules and communicates using multiplex signals.

- aftertreatment NOx sensors
- engine VGT
- EGR control module
- implement
- transmission.

Two protocols typically exist for identifying fault codes on machine systems. The first is J-1587 using a J-1708 two-wire data bus. J-1587 began being used by heavy-duty and most medium-duty vehicles built after 1985. Up to 1995, individual OEMs used their own unique diagnostic connectors. J-1587, used primarily from 1996 to 2001, is easily identified by the six-pin diagnostic connectors. Beginning in 2001, most OEMs switched to a more sophisticated J-1939 standard, which can be recognized by a nine-pin diagnostic connector. Both the J-1587/1708 and the J-1939 network connections are found in the nine-pin DLC. A specific standard exists in both protocols for identifying faults detected by the CANbus modules. Machines built using ISO standards used by European manufacturers use a different type of connector. If a machine is built and does not require meeting minimum emission standards, no particular type of diagnostic connector is required.

► TECHNICIAN TIP

To validate a repair for a fault detected by the comprehensive component monitor (CCM), start the engine and let it idle for one minute. The ECM will turn off the yellow MIL when the diagnostic monitor has run. If a CCM is evaluating electrical circuits, the light will switch off after the MIL has been illuminated for five seconds. For other faults, the ECM will typically turn off the MIL after three consecutive ignition cycles that the diagnostic monitor runs and passes.

Proprietary Blink and Flash Codes

Manufacturers are not bound to report faults by exclusively using CANbus codes. Specialized equipment and systems can use proprietary codes, meaning that the OEM is free to define its own non-emissions-related fault codes. Blink codes are dash lights that will blink, or flash, proprietary fault codes usually by using the red and amber warning lights.

Two- and three-digit codes commonly report faults. A typical arrangement to obtain blink codes based on a proprietary code will require switching on a diagnostics switch. A warning lamp flashes to indicate a fault code. Next, the stop lamp flashes out the hundredth, tenth, and single digits of the fault code. A short pause separates the flashing of each digit, and a longer pause separates codes. Warning lamps may switch between active and inactive codes by flashing either the red warning light for active or the yellow warning light for inactive. If no fault codes are active, the warning lamps remain lit. Some manufacturers may not use a diagnostic switch to obtain blink codes. Instead, the ignition key is switched on and off in a specific sequence to produce diagnostic blink codes. Rather than using a diagnostic switch, other machines may require creating the correct conditions—such as key-on engine-off (KOEO), park brakes set, or

depressing switches—to prompt blink codes. Instrument clusters are network devices that can also receive and report fault codes in the absence of a readily available service tool.

J-1587 Fault Code Construction

The SAE (American Society of Automotive Engineers) developed the fault code reporting standard, referred to as J-1587. Six- and nine-pin diagnostic connectors carry J-1587 codes, but six-pin connectors do not include J-1939, the latest protocol. J-1587 fault codes are specifically constructed to help technicians easily isolate faults. The codes have four parts:

1. message identifier (MID) (also called module identifier)
2. parameter identifier (PID)
3. system identifier (SID)
4. failure mode identifier (FIGURE 20-7).

Other fault code identifiers specific to an OEM may include the following:

- Proprietary parameter identification (PPID) is an OEM identification of a parameter or value used only by that manufacturer.
- Proprietary subsystem identification description (PSID) is an OEM-unique component identification.

A **message identifier (MID)** identifies which module is reporting the fault. MIDs are the first byte or character of each message that identifies which control module on the J-1587 serial communication link originated the information. A standard list of message or module identifiers exists for all machines regardless of manufacturer.

1. A **system identifier (SID)** indicates a specific failed component or replaceable subsystem associated with a fault. There are several SIDs.
2. A **parameter identifier (PID)** is a value or identifier of an item being reported with fault data. J-1957 uses hundreds of PIDs.
3. The **failure mode identifier (FMI)** describes the type of failure detected in the subsystem and identified by the PID or SID. The FMI and the PID or SID, not both, combine to form a J-1957 diagnostic code. The general format of a fault message is MID-PID/SID-FMI.

Now consider code 128-101-002. It breaks down as follows:

- 128: engine
- 101: intake boost pressure
- 002: data erratic, intermittent, or incorrect.

OEM proprietary fault codes would include the following:

- 54: Detroit Diesel
- 84: Caterpillar
- 115: Cummins.

J-1939 Fault Code Construction

J-1939 codes have a construction similar to J-1957 but are far more comprehensive. J-1939 uses the CANbus protocol, which

FIGURE 20-7 Construction of J-1587 fault codes.

permits any electronic control module to transmit a message over the network when the bus is idle or not transmitting other information. Similar to J-1957, every message includes an identifier that defines who sent it, what data is contained within the message, and the priority, or seriousness, of the fault or problem. Instead of a PID and SID, J-1939 uses only a **suspect parameter number (SPN)** (FIGURE 20-8).

FIGURE 20-8 J-1939 codes on a dash-mounted device the operator uses to check codes. Note the occurrence count (“OC: 1”) in the top right corner of the screen. **A.** Suspect parameter number. **B.** Fault code identifier.

The SPN is the smallest identifiable fault. Next, a failure mode indicator (FMI) notes the type of failure that has been detected.

The **source address (SA)** field designates the control module that is sending the message table (TABLE 20-1 and TABLE 20-2).

TABLE 20-1 J-1939 SAs	
SID	Description
1	Engine
3	Transmission
11	Brakes

TABLE 20-2 Comparing J-1939 and J-1587 Fault Codes	
J-1939	J-1587
Source address (SA)	Message identifier (MID)
Suspect parameter number (SPN) (thousands of combinations)	Parameter identifier (PID) (hundreds of combinations)
N/A	System identifier (SID)
Fault mode indicator (0–31)	Fault mode indicator (0–15)

Construction of J-1939 Fault Codes SPN + FMI + OC

FIGURE 20-9 A J-1939 code uses SPNs and FMIs. An occurrence count (OC) may accompany the code on OEM software.

Suspect Parameter Number

The suspect parameter number (SPN) combines elements of J-1957 PIDs and SIDs. The SPN is used for multiple diagnostic purposes:

- identifying the least repairable subsystem that has failed
- identifying subsystems and/or assemblies that may not have completely failed but may be exhibiting abnormal operating performance
- identifying a particular event or condition that requires reporting
- reporting a component and nonstandard failure mode (FIGURE 20-9 and TABLE 20-3).

J-1939 FMI

The FMI defines the type of failure detected in the subsystem identified by an SPN. The failure may not be an electrical failure but may instead be a subsystem failure or condition needing to be reported to the service technician and, perhaps, the operator. Conditions can include system events or statuses (TABLE 20-4 and TABLE 20-5).

Occurrence Count (OC)

The OC represents the number of times a fault combination of SPN/FMI has taken place.

TABLE 20-3 Example SPNs

SPN	Description
031	Transmission range position
156	Injector timing rail 1 pressure
190	Engine speed
512	Driver's demand engine—percent torque
513	Actual engine—percent torque
639	J-1939 network
899	Engine torque mode
1483	Source address of controlling device for engine control
1675	Engine starter mode
2432	Engine demand—percent torque

TABLE 20-4 SAE J-1939 FMIs

FMI	SAE Text
0	Data valid but above normal operational range—most severe level
1	Data valid but below normal operational range—most severe level
2	Data erratic, intermittent, or incorrect
3	Voltage above normal or shorted to high source
4	Voltage below normal or shorted to low source
5	Current below normal or open circuit
6	Current above normal or grounded circuit
7	Mechanical system not responding or out of adjustment
8	Abnormal frequency or pulse width or period
9	Abnormal update rate
10	Abnormal rate of change
11	Root cause not known
12	Bad intelligent device or component
13	Out of calibration
14	Special instructions
15	Data valid but above normal operating range—least severe level
16	Data valid but above normal operating range—moderately severe level
17	Data valid but below normal operating range—least severe level
18	Data valid but below normal operating range—moderately severe level
19	Received network data in error
20–30	Reserved for SAE assignment
31	Condition exists

Parameter Group Number

SPN, source addresses, and FMI information are part of a larger J-1939 message called the **parameter group number (PGN)**. PGN information includes commands, data, requests,

TABLE 20-5 Comparison of J-1939 SPN and J-1708/J-1587 Fault Codes

Description	J-1939		J-1708/J-1587

acknowledgments, and negative acknowledgments, and fault codes. The package of serial data is transmitted over the CANbus. SPNs are assigned to each individual parameter within the PGN. This means each PGN will contain a different set of SPNs. For example, PGN 61444 is the electronic engine controller 1. Hundreds of possible messages can originate from this component because of the number of sensors and the complexity of the system and its operation (**FIGURE 20-10** and **TABLE 20-6**).

PGN 614444 includes the following SPNs:

- engine torque mode
- operator demand engine—percent torque actual engine—percent torque
- engine speed
- engine starter mode
- engine demand—percent torque.

Message Priority

To prevent message signals from canceling out one another, signal collisions are avoided through an arbitration process that takes place while the PGN identifier is transmitted. The lower the first number is in the message, the greater importance attached to the information, requiring all other modules to listen while the information is transmitted:

- Highest priority: This is used for situations that require immediate action by the receiving device in order to provide safe vehicle operation (e.g., braking systems). This level of priority is used only in safety critical conditions.
- High priority: This is used for control situations that require prompt action in order to provide safe vehicle operation (e.g., a transmission performing an upshift, which requires a change in engine speed to control gear synchronization of damage to clutch packs) (**TABLE 20-7**).

FIGURE 20-10 A J-1939 fault code is 29 bits long. The check sum (CM) field is a function of the other numbers in the code. If another module reads the code and the CM does not match, the data is rejected.

TABLE 20-6 Example PGNs

PGN	Description
61441	Electronic Brake Controller I (EBCI)
61442	Electronic Transmission Controller I (ETCI)
61444	Electronic Engine Controller I (EECI)
65225	Service Information (SERV)

TABLE 20-7 Priority Fault Codes

Priority	Description
1 and 2	Reserved for messages that require immediate access to the bus
3 and 4	Reserved for messages that require prompt access to the bus in order to prevent severe mechanical damage.
5 and 6	Reserved for messages that directly affect the economical or efficient operation of the vehicle
7 and 8	All other messages not fitting into the previous priority categories

Wrap-Up

Ready for Review

- ▶ Understanding the operating principles of electronic control systems is foundational for choosing diagnostic strategies, using service tools effectively, and making sound repair recommendations.
- ▶ Emission standards established for off-road diesels beginning in the late 1994 have required a level of precision for engine control that is possible only through the extensive use of electronics. Electrical devices now perform the work once done by fuel system camshafts, levers, springs, flyweights, and other assorted mechanical devices.
- ▶ Electronic systems do not have many moving parts to wear out, but the systems can be complex. When something goes wrong with a component or circuit, identifying the problem without some built-in self-diagnostic capabilities can be extremely time-consuming and difficult.
- ▶ With built-in electronic self-monitoring functions, electrical systems possess the capability to check the operation of circuits and electrical devices, evaluate the rationality of data, and identify problems as they occur.
- ▶ Traditional self-diagnostic strategies focus on specific areas of machine control, such as the engine, implement, and transmissions.
- ▶ Model-based diagnostics compare system and component behaviors to expected patterns of operation.
- ▶ A fault is a deviation of at least one characteristic property of the system from its standard behavior.
- ▶ A failure is a fault that permanently interrupts a system's ability to perform a required function under specified operating conditions.

- ▶ A disturbance is an unknown and uncontrolled input acting on the system.
- ▶ Fault detection is a diagnostic strategy to determine whether faults are present in the system.
- ▶ Fault isolation is determining the location of the fault.
- ▶ When a fault is detected, fault accommodation, which is also known as an adaptive strategy, reconfigures the system operation or substitutes suspect data with default data to maintain normal system functionality even with the fault.
- ▶ When electrical faults or system problems occur in control systems, electronic control modules log DTCs in the system memory, which are read through an instrument display cluster or blink codes or retrieved by a scanner or personal computer connected to the machine DLC.
- ▶ The SAE developed the fault code reporting standard, referred to as J-1587.
- ▶ J-1939 uses the CANbus protocol, which permits any electronic control module to transmit a message over the network when the data bus is idle or not transmitting other information. Every message includes an identifier that defines who sent it, what data is contained in the message, and the priority, or seriousness, of the fault or problem.

Key Terms

active fault A fault that is currently taking place and uninterrupted in action.

blink code A method of providing fault code data for a specific system, which involves counting the number of flashes from a warning lamp and observing longer pauses between the light blinks.

diagnostic link connector (DLC) The connection point for electronic service tools used to access fault codes and other information provided by chassis electronic control modules.

diagnostic trouble code (DTC) A code logged by the electronic control module when electrical faults or system problems occur in commercial vehicle control systems.

failure mode identifier (FMI) The type of failure detected in the SPN, PID, or SID.

historical fault A fault that took place at one time but that is now corrected and no longer active.

incipient fault A fault that is the result of system or component deterioration.

intermittent fault A fault that is not ongoing and can be both active and historical.

message identifier (MID) also called module identifier The electronic control module that has identified a fault. J-1587 protocols use MIDs.

off-board diagnostics Procedures to isolate a fault based on fault code information, including retrieving fault code information, monitoring system operation, performing actuator tests and pinpoint electrical tests, and inspecting components.

onboard diagnostics (OBD) Self-diagnostic capabilities of electronic control modules that allow them to evaluate voltage

and current levels of circuits to which they are connected and determine whether data is in the correct operational range.

OBD manager Software that identifies fault codes and ensures emissions systems are operating correctly.

out-of-range monitoring Validating sensor data to verify that a system is operating within an expected range for a given operating condition.

parameter group number (PGN) A package of serial data transmitted over the CAN network that includes SPN, source addresses, and FMI, as well as commands, data, requests, acknowledgments, negative acknowledgments, and fault codes.

parameter identifier (PID) A value or identifier of an item being reported with fault data.

source address (SA) The field that designates which control module is sending the message.

suspect parameter number (SPN) A numerical identifier that defines the data in a fault message and the priority of the fault.

system identifier (SID) A fault code used by J-1587 protocols that identifies which subsystem has failed.

telematics A branch of information technology that uses specialized applications for the long-distance transmission of information to and from a vehicle.

Review Questions

1. Emission standards established for off-road diesels began in _____.
 - a. 1994
 - b. 1992
 - c. 2001
 - d. 2014
2. The OBD (onboard diagnostics) system can take one of two self-diagnostic approaches to identifying faults. The system can either use traditional self-diagnostic strategies or use _____.
 - a. a manufacturer-based approach
 - b. a model-based approach
 - c. manufacturer-based diagnostics
 - d. case-based reasoning
3. _____ is/are an adaptive strategy that reconfigures the system operation or substitutes suspect data with default data to maintain normal system functionality even with the fault.
 - a. Fault codes
 - b. Fault accommodation
 - c. Fault detection
 - d. Disturbance
4. System self-diagnostic checks are generally performed by limit checking of _____ or circuit data.
 - a. circuits
 - b. sensors
 - c. controllers
 - d. monitors
5. Data from a sensor as simple as the coolant temperature are even more critical to operation because _____ that

evaluate emissions-control devices will run only after an engine has reached operating temperature.

- a. monitors
 - b. circuits
 - c. sensors
 - d. controllers
6. In the OBD system, a _____ is a deviation of at least one characteristic property of the system from its standard behavior.
 - a. monitor
 - b. fault
 - c. defect
 - d. failure
 7. What type of OBD fault is not ongoing and can be both active and historical?
 - a. Incipient
 - b. Controlling
 - c. Intermittent
 - d. Constant
 8. What is an unknown and uncontrolled input acting on the OBD system?
 - a. Failure
 - b. Disturbance
 - c. Fault
 - d. Monitor
 9. This type of fault is currently taking place and is uninterrupted in action.
 - a. Failure
 - b. Disturbance
 - c. Active
 - d. Incipient
 10. A message identifier (MID) identifies which _____ is reporting the fault.
 - a. component
 - b. sensor
 - c. switch
 - d. module
- c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A says that an incipient fault is not ongoing and can be both active and historical. Technician B says that an incipient fault is a fault that is the result of system or component deterioration. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 4. Technician A says a suspect parameter number (SPN) is a fault code used by J-1587 protocols that identifies which subsystem has failed. Technician B says a system identifier (SID) is a numerical identifier that defines the data in a fault message and the priority of the fault. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 5. Technician A says that some manufacturers may use their own codes because they are not bound to CANbus. Technician B says that all manufacturers must use CANbus. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 6. Technician A says that a system identifier (SID) indicates a specific failed component. Technician B says that a parameter identifier (PID) is a value or identifier of an item being reported with fault data. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 7. Technician A says that J-1939 uses the CANbus protocol, which permits any electronic control module to transmit a message over the network. Technician B says that J-1939 still uses parameter identifier (PID) as a value or identifier of an item being reported with fault data. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 8. Technician A says that the suspect parameter number (SPN) combines elements of J-1957 PIDs and SIDs. Technician B says that the SPN is used for multiple diagnostic purposes. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
 9. Two technicians are discussing J-1939 fault code construction. Technician A says that parameter group number (PGN) information includes commands, data, requests, acknowledgments, and negative acknowledgments, and

ASE Technician A/Technician B Style Questions

1. Two technicians are discussing OBD for machines. Technician A says that the simplest, most familiar definition is the diagnostic function of electronic control systems to identify or self-diagnose system faults and report fault codes. Technician B says the OBD will only send blink codes to the display. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says that a fault is a deviation of at least one characteristic property of the system from its standard behavior. Technician B says that a historical fault took place at one time and can never be active again. Who is correct?
 - a. Technician A
 - b. Technician B

fault codes. Technician B says that parameter group number (PGN) information includes commands, data, and requests only. Who is correct?

- a.** Technician A
 - b.** Technician B
 - c.** Both Technician A and Technician B
 - d.** Neither Technician A nor Technician B
- 10.** Two technicians are discussing J-1939 fault code construction. Technician A says that to prevent message sig-

nals from canceling out one another, signal collisions are avoided through an arbitration process. Technician B says that high priority is used for control situations that require prompt action in order to provide safe vehicle operation. Who is correct?

- a.** Technician A
- b.** Technician B
- c.** Both Technician A and Technician B
- d.** Neither Technician A nor Technician B

CHAPTER 21

Automated Machines, Telematics, and Autonomous Machine Operation

Knowledge Objectives

After reading this chapter, you will be able to:

- **K21001** Identify and describe the types, functions, and applications of autonomous and self-steering machines.
- **K21002** Identify and describe the purpose, function, construction, and operating principles of autonomous drive systems.
- **K21003** Identify and describe principles of machine position estimation, perception, and site mapping.
- **K21004** Identify and describe principles of machine motion planning.
- **K21005** Identify and explain the principles, types, and applications of vehicle telemetry.
- **K21006** Outline the principals involved in the integration of global positioning system (GPS) signals to autonomous machine control systems.
- **K21007** Explain the purpose, operation, and construction of autosteering, braking, and throttle output components.

Skills Objectives

After reading this chapter, you will be able to:

- **S21001** Perform OEM recommended diagnostic tests of autonomous drive control systems.
- **S21002** Locate and follow OEM service procedures for servicing autonomous drive systems.

► Applications of Autonomous and Self-Steering Machines

K21001

Automation, which is the use of control systems reducing or eliminating human intervention to operate machinery, is a rapidly evolving technology sector that has made its way into the off-road equipment industry. While on the road self-driving autonomous automobiles and trucks have received considerable media attention, the innovations are not new in comparison to off-road machinery. For years before the availability of a single autonomous car or truck for purchase by consumers, remote-controlled, self-steering, self-navigating, semi-autonomous, and fully autonomous off-road equipment was already being used in the agricultural, forestry, construction, and mining industries. In fact, many of the technologies and operational concepts used by on-highway vehicles were pioneered during the development of off-road equipment having various levels of driver-assisted, autonomous-operation capability. Farm tractors, mine trucks, and bulldozers with fully autonomous control systems—that is,

off-road equipment capable of sensing its environment and navigating without human input—have been on the market since 2013 (**FIGURE 21-1**). Off-road products like these place fully autonomous off-road machines at least seven of eight years ahead of when the first fully autonomous cars are expected in the showrooms. **Fully autonomous operation**, the most advanced category of equipment without direct human “hands-on control,” has evolved from a technological history of machines with **global positioning system (GPS)** guidance and self-steering systems used for over two decades.

For even longer than the use of semi-autonomous or even autonomous machine operation, mining equipment has regularly used simpler remote-control capabilities. These remote-control systems where an operator can use a set of controls that electronically duplicates actual machine controls enable operators to work at a distance and avoid potentially hazardous worksite conditions. Instead, radio signals transmitted over no further than line of site or Internet-based communication over even further distances can transmit operator commands to the machine without any detectable lag.

FIGURE 21-1 Major components of an automated guidance system found on an agricultural tractor.

You Are the Mobile Heavy Technician

Working at a construction business with a wide mix of earth-moving and excavating machines, you are tasked with retrofitting several pieces of older equipment with new telematics- and GPS-based technology to improve machine efficiency and better invoice working hours on the job. For this pilot program, you are allocated one wheel loader, an excavator, and two bulldozers and are requested to research and develop potential technical solutions for each of the machines. As you prepare your proposal, consider the following topics to compare solutions for each machine:

1. Outline the benefits to the operation for providing telematics and machine location data?
2. What types of retrofit components may be required for each machine to provide an indicate-only type of **computer-aided earth-moving system (CAES)**?
3. What are the advantages and disadvantages of single and dual GPS antenna/receiver systems?

Even without the use of sophisticated semi-autonomous and fully autonomous control, equipment operations are rapidly incorporating advanced electronic communications into machinery. The integration of **telematics**—that is, the transmission and receiving information from remote objects over cell phone or satellite communication networks—is widely recognized as delivering a tremendous number of benefits for technicians and equipment managers. Using telematics, machine data combined with GPS signals capable of tracking and navigating equipment anywhere, is viewed through web portals after it's analyzed with special software applications. The analysis supplies subscribers with an enormous amount of decision-making information related to operating more productive machines maintained with superior management, service, and maintenance practices (**FIGURE 21-2**).

Automated machine operation, remote-control, operator-assisted control, and the use of telematics encompass varying levels of sophistication and integration into machine systems. To help technicians understand these systems in order to effectively diagnose and service the equipment, this chapter will identify and examine machine technologies essential for enabling, remote-controlled, semi-autonomous, and fully autonomous machine operation. Operating principles of automated machine steering, positioning based on GPS signals, environment sensing, object detection, implement control, information processing, and interconnected machine networks are several of the major topics covered in this chapter. Highlighted too are various OEM machine management system software suites used to service what many today refer to as “smart-iron” (**FIGURE 21-3**).

FIGURE 21-2 Diagnostic information transmitted from the machine helps technicians remotely diagnose a problem and determine what parts to bring on a service call.

► An Overview of Automated Machine Operation

K21002

Operating any type of off-road equipment is an extremely demanding task. The operator must not only safely steer, brake, and turn over rugged, unmarked pathways but also perform these tasks well while controlling implements, blades, and other attachments. In addition to the high level of skill that operators need to operate the machine implements, they must ensure that during repetitive tasks, they remain attentive and are

FIGURE 21-3 Key technologies of “smart iron” or the connected machine.

productive. Efficient operations are achievable only when the machine and operator are working quickly, at the highest skill level, using the least amount of fuel, and minimizing the likelihood of any potential damage to the machine, with little to no downtime. That means interruptions to the work cycle are kept to a minimum and that operations can take place during the day and night regardless of whether the work site is busy; crowded with other equipment and people; or noisy, dusty, and poorly lit. These demands impose enormous expectations that even the most skilled operator cannot deliver. Any kind of assistance or control method of safely reducing the amount of human intervention can only help to improve productivity and safety.

Overall, automating off-road machine functions has tremendous potential to increase productivity and improve the quality, accuracy, and precision of work. Automating machine steering, navigation, positioning, object avoidance, implement control, or any driving function can also increase worker and site safety, extend machine durability, and provide a wealth of features and data to equipment managers. When applied to off-road equipment, the greatest advantages of automation are not only increased production efficiency but also reduced labor cost. With various degrees of automation, machines can operate longer and faster. Rather than replace operator labor, automating simpler tasks allows operators to turn their attention to more critical, complex functions. At least, the learning curve for new operators can be reduced.

Machine automation doesn't always imply fully autonomous operation. Instead, it refers to varying degrees of machine operation performed without human intervention. Each off-road equipment industry has its own unique priorities in terms of automating functions. This means each application's system will use different types of sensors and programming objectives. In agriculture, a field tractor should not run over crops; it should minimize overlaps and skips while seeding, fertilizing, applying pesticides, or cultivating while the operator continuously monitors equipment performance. Tractors tow implements, and work is performed during the night. For a farm tractor, automating priorities are precise navigation, object recognition of plants and field hazards, and self-steering capabilities. Mining operations use machines to break and remove rock, then stockpile ore and waste materials. These sites are inherently dangerous since equipment runs through narrow tunnels, accompanied by blasting dangers, wall collapses, and explosion hazards. Automating machine functions that remove the operator from the cab can greatly improve worker safety (FIGURE 21-4). In mining, remotely operated mining equipment controlled by an operator at an offsite location that uses cameras and other sensors is an automation priority.

More elaborate machine operation is demanded by earth-moving equipment. The latest automated construction equipment uses bulldozers with automatically controlled blades that move to match digital 3D CAD drawings (FIGURE 21-5). CAESs integrate GPS data into a machine's hydraulic controls and guidance to autonomously operate a machine's hydraulic implements, such as buckets, shovels, booms, sticks, and blades. As the worksite features change, the machine transmits data

FIGURE 21-4 Remote control minimizes operator safety hazards while simultaneously providing a more comfortable and productive work environment.

FIGURE 21-5 3D site drawing can be transmitted to a machine for precision blade control.

about the work it has completed to enable software to update worksite maps, rendering the latest terrain and site conditions. The enormous increase in machine productivity using CAES means that precision blade or implement control using GPS locating services is a priority accessory for most new off-road equipment.

Whether it's on the farm, in the forest, underground, or clearing dirt for a roadway, the telematically connected machine can transmit diagnostic data. Machine position and usage is easily tracked by OEM software. Popular examples of machine monitoring and control software include Caterpillar's Cat Command System, Komatsu's Intelligent Machine Control, Case's SiteWatch, and John Deere's WorkSite. The following are functions common to equipment management software:

- identifying equipment abuse of improper machine operation prior to failure
- performing remote software upgrades to eliminate the need for technician service calls

FIGURE 21-6 The typology or shape of connections for a telematics machine monitoring software suite.

- dispatching technicians with the correct parts to make a service call
- locating missing equipment moved outside a jobsite with GPS geofence notifications.

Machine data can be collected and typically transmitted via the Internet or cell phone signals to supply any measurable machine data, including information from engines, powertrains, work implements, hydraulic system controls, or machine positions (**FIGURE 21-6**). The technology that enables data collection and electronic transmission for display on a remote computer screen or web page is called telematics. Data about fuel consumption, fuel level, and pending faults can enable scheduling for refueling or service. Reporting various temperature, speed, and pressure data to equipment management software can relieve an operator's attention for more important work (**FIGURE 21-7**).

► Classifications of Autonomous Systems

K21003

Defined in the simplest way, automation is the use of control systems to reduce or eliminate human intervention. The term “autonomous” encompasses a wide range of technology applicable to the entire machine or its subsystems. An example of

FIGURE 21-7 A telematics system transmitted this recording of a fault associated with a machine's exhaust gas recirculation (EGR) system for analysis by a technician.

automated subsystem is parking, braking, collision avoidance, and driver assistance systems that can to some degree automatically intervene to prevent or reduce damage and injury during an emergency. Goals of fully autonomous equipment control take the operator completely out from behind the wheel and even eliminate the cab. Equipment is aware of its position and surroundings and able to adapt to changing conditions. Specific tasks performed by the machine are automatically accomplished with precision. Automated equipment designs provide a greater opportunity to improve energy efficiency many times over current benchmarks while producing zero emissions, with

the bonus of never having an accident or causing an injury. Even though the machine may have full autonomous capability, human behavior can be integrated into machine operations. For example, machines that are aware of an operator's workloads or shift change time can drop off an operator and pick up another at a predetermined time and place. This feature, called **Humans in the Loop (HITL)**, includes people who provide assistance with autonomous function or other machine support, such as a repair technician.

There is no formal classification system yet for categorizing the level of off-road machine automation, but there is some correspondence to on-road, autonomous, or self-driving vehicle categories defined by the SAE (International Society for Automotive Engineers), which encompass some or all of these levels of automation. In 2014, **SAE J-3016** was adopted into legislation for on-highway vehicles. It classifies vehicle automation into five categories depending on the level of human control or intervention.

Autonomous Vehicle Standard

Level 0: Automated system has no vehicle control but may issue warnings.

Level 1: Driver must be ready to take control at any time. Automated system may include features such as adaptive cruise control (ACC), parking assistance with automated steering, and lane keeping assistance (LKA) Type II in any combination.

Level 2: The driver is obliged to detect objects and events and respond if the automated system fails to respond properly. The automated system executes accelerating, braking, and steering. The automated system can deactivate immediately upon takeover by the driver.

Level 3: Within known, limited environments (such as freeways), the driver can safely turn their attention away from driving tasks, but must still be prepared to take control when needed.

Level 4: The automated system can control the vehicle in all but a few environments, such as severe weather. The driver must enable the automated system only when it is safe to do so. When enabled, driver attention is not required.

Level 5: Other than setting the destination and starting the system, no human intervention is required. The automatic system can drive to any location where it is legal to drive and make its own decisions.

Types of Off-Road Autonomous Control Systems

The term "autonomous vehicle control" is generally understood to be similar to levels 3 through 5 of the J13016 standard, but in off-road machines these same designations have not yet developed. Driver-assisted control is taken to mean semi-autonomous control, and there are various degrees of capabilities and technological sophistication within that category. However, decades before Google and Uber ever fielded a self-driving car, agricultural equipment manufacturers like John Deere were marketing self-driving machinery. In

fairness, the development pathway for autonomous and semi-autonomous machines has comparatively fewer obstacles. Using automated machinery on private property rather than in a complex environment of roadways traveled at high speeds meant reduced legal liability to manufacturers over concerns about errant equipment. Since agricultural fields have fewer potential obstacles than a street or highway filled with other machines and people operating at high speeds, the potential hazards to navigate are comparatively limited. Unlike streets and highways, detailed maps of rural fields with relatively straight rows of crops are not necessary, and equipment needs to move more often only in straight lines and turn after reaching the end of each row. The absence of regulations over autonomous and semi-autonomous off-road vehicles, such as those used in farming, has also helped the machinery to quickly become adopted onto the farm.

A more functional method to categorize or designate the types of semi-autonomous and autonomous machinery for tasks such as farming, earth-moving, and other off-road applications is to describe the equipment in terms of its use in steering, navigating, object recognition, and integrating machine control functions. Each has a different level of human control or need for supervision and approaches the question about what method best enables human interaction to make the machine more productive and reliable for any given task. These broad categories include the following:

1. Remote control (RC)

RC is a control system that removes the operator from the machine whenever the working conditions pose safety hazards. An equipment operator instead stands in line of sight or has direct visual contact while using the remote control to operate the machine (**FIGURE 21-8**).

2. Telematics or tele-operated control

Telematics refers to technology that sends, receives, and stores machine information through telecommunication devices such as radio, wireless Internet, and satellite or cell phone signals. While telematics has traditionally

FIGURE 21-8 A remote-control panel wirelessly communicates with the machine. Controls on the machine are duplicated using the remote-control panel used by the operator.

involved taking equipment or vehicle information and transmitting it to a website where it can be viewed, two-way or bidirectional telematics communications enables the operator to control machines at a further distance than line-of-site remote control. Machine-to-machine communication is also accomplished using telematics communication principles.

3. Self-steering control

Self-steering machine control refers to a collection of early stand-alone driver-assisted guidance control technologies that use external physical guidance devices such as foam markers, light ropes, inductive wires, or reflective tape. An electric motor-driven steering wheel or electrically controlled hydraulic steering control valve enables hands-off steering control of the machine. An automatic sensing system will use the physical marking system to provide a path for a machine to follow. Another method is to use a dead reckoning navigation system. This navigating system calculates a machine's current position by using a previously determined position or coordinating and updating that position based on known or estimated speeds over time. **Dead reckoning systems** depend only on vehicle sensors such as speed, steering angle, and even a magnetic compass. A radio-operated node or signal transmitter may provide a reference point. Prior to the introduction of GPS systems, agricultural vehicles used self-steering guidance systems for **precision farmer techniques**, which

are techniques developed to precisely cultivate, seed, fertilize, and harvest crops. To install an assisted steering system motor, follow the steps in **SKILL DRILL 21-I**.

4. Self-steering + GPS navigation

The GPS, which uses satellites to identify positioning and to navigate, have introduced much of the potential growth in off-road equipment automation. Introduced in the early 1990s for civilian use after being formerly used exclusively by the military, GPS navigation is used to provide a critical navigational input to microprocessor-controlled steering equipment. Again, these steering systems use electric motors driving the steering wheel, steering gears, or the electrohydraulic controls of the steering hydraulics. With accuracy to within $\frac{1}{2}$ inch or 2 cm of a machine's position, these systems are often called integral autosteer and are regarded as the most accurate way to control the machine. The technology is commonly available as a retrofit, but virtually all manufacturers offer it as a machine accessory option, installed at the factory.

5. Self-navigation + object avoidance system

With advancements in more powerful image-recognition software, position sensors, cameras, and laser perception systems, off-road machinery can integrate data acquired from the worksite with decision-making programming. The latest automation systems can gather, analyze, and

SKILL DRILL 21-I Installing an Assisted Steering System Motor

A popular GPS-controlled assisted steering system requires installing an anti-rotation bracket and a drive motor in the steering column. The following are general steps for installing the steering motor of a Trimble EZ EZ-Pilot-assisted steer system:

1. Disassemble the steering column by removing brackets and necessary covers to install the anti-rotation bracket. The bracket is used to support the steering motor on the steering shaft.
2. Install the anti-rotation bracket onto the steering column.
3. Loosen and remove the steering wheel from the splined steering shaft.
4. Assemble the EZ-Pilot drive motor by fastening the splined lower plate adapter to the bottom of the motor.
5. Fasten the anti-rotation pins to bottom plate of the motor at 11 and 1 o'clock positions.
6. Place the motor assembly onto the steering shaft with the motor's connector at a 2 o'clock position. The splines of the motor adapter and steering shaft must align. The anti-rotation pins on the bottom of the motor should be at the 12 o'clock and 3 o'clock positions. Do not force the motor onto the steering shaft. Instead, wiggle the motor while gently pushing downward.
7. Install a split lock washer and hex nut to hold the motor onto the steering shaft. Torque all hardware.
8. Rotate the motor and then slide the square anti-rotation tubes onto the anti-rotation pins.
9. Install the additional steering shaft telescopic extension rod. The rod has a threaded end that tightens onto the original steering shaft.
10. Lock the extension rod with a set screw against the flat side of the steering column shaft.
11. Bolt the upper motor adapter and the spud shaft to the top of the motor.
12. Reinstall the steering wheel onto the splined spud shaft using anti-seize compound on the threads.
13. Install the nut and lock washer and torque to specification.
14. Install the GPS antenna, control module, emergency shutdown switch, alarm, and display.
15. Calibrate the unit.

interpret machine and site information to operate actuation systems responsible for moving the machine while performing specific operations. These systems consist of different navigation systems, equipment sensors, actuators, and microprocessor control units synchronized to form an autonomously operated machine. Most importantly, a system to detect and analyze objects using one or more technologies such as a sonar, radar, LIDAR (a laser device operating long similar principles of a radar), or a stereo color camera is integrated into the machine control system.

6. Platooning—machine-to-machine communication

Platooning is a machine-to-machine or inter-vehicle communication system that currently improves productivity by enabling a single operator to control the operation of multiple machines in an agriculture field operation. Most often used in machines operating on large farm fields, operators are relieved of tedious, repetitious driving routines and can instead concentrate on ensuring the accuracy of the work performed by the machines. Using autosteering, cruise control, and braking functions, one or more autonomous agriculture machines with a specific amount of lateral and longitudinal offset follow a lead machine. That means a lead machine with an operator overseeing the movement of all the machines in the field will have several other machines follow the lead tractor at a fixed space and distance. An arrangement like this is referred to as a platooning system. Platooning is enabled by connecting machines together using a **wireless CAN bridge**. The CAN bridge is the machine-to-machine communication systems collecting data from the **controller area network (CAN) bus** (shortened to CANbus) in one machine and wirelessly transmitting the information to the CANbus in the trailing machine (**FIGURE 21-9**). The CANbus contains data transmitted by every control module, including vehicle speed.

FIGURE 21-9 Platooning transmits CAN data from the lead machine to the trailing machine to maintain a precise lateral offset and distance of the trailing machine behind the lead unit.

To coordinate machine positioning, the geographical position of the lead tractor is transmitted continuously by wireless modems to the trailing machine to provide locating reference points to the trailing machine. Using the navigation coordinates of the lead machine, a path is planned for the trailing machine to follow at the specific calculated speed and steering angle relative to the lead machine. To ensure the operator-less trailing tractor follows the correct course, software with speed and motion control algorithms are built into the machine control modules. To install a CAN bridge with GPS, follow the steps in **SKILL DRILL 21-2**.

Automated System Architecture

To understand the operation of various levels of automated machine operation, it's important to identify the building blocks of any automated system (**FIGURE 21-10**). There are three critical elements of automated system architecture:

1. sensing-perception
2. decision-making or processing
3. actuation or output.

Sensing function responsibility is to collect information from the environment using a variety of sensors. The types of sensors can include cameras for image collection, GPS, and inertial guidance systems that sense machine and implement position. **Inertial guidance systems** are navigation systems used when GPS or communication with a base station is unavailable to track machine position and orientation relative to a known starting point, orientation, and velocity. Inertial guidance systems use dead reckoning navigation, which uses machine sensors or instruments measuring speed, direction, and rate of acceleration. A simple compass would be an example of an instrument used by an inertial guidance system. Not only are sensors needed for navigation, but they are also specifically adapted for a machine's task. An excavator, for example, will use sensors on the boom and stick to sense the position of the bucket. A road grader will use sensors to determine the position, direction, height and angle of the blade or moldboard. Sensors used to identify and pick tomatoes will be different from those involved in the task of grading a roadway, cutting down a tree, or moving material to a conveyor belt (**FIGURE 21-11**).

The processing or decision-making system is often sophisticated software responsible for interpreting sensor data and providing an appropriate output signal. For example, **object or collision avoidance systems** identify objects such as a deep hole capable of damaging or even swallowing a machine or a worker. The system may even read a speed limit sign. Object or collision avoidance is the job of the decision-making system. It will take sensor data and process the information through a specific set of procedures, rules, or mathematical algorithms (algorithms are mathematical formulas used to solve a problem). A system response determines whether the machine should steer around an object, stop the machine, or change the machine speed if it is not traveling at the correct velocity. Software algorithms may determine the difference between picking or ignoring a tomato

SKILL DRILL 21-2 Installing a CAN Bridge with GPS

CAN bridges wirelessly connect a machine's controlled area network to a wireless local area network (WLAN) or a cellular or Bluetooth network. They can also be used to connect machine-to-machine CAN networks such as those needed for configuring lead and trailing machines into platoons. The CAN bridge module interface connects to the machine and is configured with a PC that is running software designed to select and modify module features. When connected to a WLAN, network devices such as computers, smartphones, or tablets can manage and evaluate CAN data through a bidirectional communication enabled by the module. CAN bridges serve as a replacement for a CAN cable for more efficient and dependable communication between a machine and management tools.

The following is an overview of basic installation instructions for a CAN bridge module:

1. Unpack the unit and identify plugs for the power supply, antenna, and CAN connector.
2. Mount the module in the chassis and connect the main power harness to the chassis constant battery and switched battery supply. Do not install an external ground, since it may interfere with the reverse-polarity protection circuits.
3. Ensure the device is switched off and then connect the network data bus to a stub connector having CAN-L and CAN-H signals. Ensure that the polarity of the network signal matches the units CAN-H and CAN-L connector.
4. Ensure that the device's power supply is switched off and connect the GPS, 3G cellular, or combination antenna cable to the module.
5. To maximize the performance of the GPS receiver; mount the GPS antenna in a place where it has an unobstructed view of the sky and is level with the horizon. If more than one antenna is used, mount them least 2 m away from each other to minimize interference.
6. Connect CAN module to a PC and establish a connection between the module and PC.
7. Configure the CAN bridge for various options, such as the types of devices it can communicate with and the Internet, cellular, and telematics service providers.

FIGURE 21-10 Three major elements making up system architecture for any level of autonomous machine operation.

based on the object size and color. A tree may be harvested if it fits the appropriate algorithm for selection based on diameter and location.

After processing system sensor data, decisions are made and output signals or messages are transmitted to the actuation systems when required. The machine may need to change

direction or speed based on information processed by the decision-making system. The machine may also require moving a hydraulic cylinder to change the position of a grader blade, dump a bucket, or change the angle of a towed implement. Electrical signals from the processing system's electronic control units are converted by the actuation system into

FIGURE 21-11 A GPS transmitter mounted on a pole and attached to the blade of a grader can sense place movement in three axes—x, y, and z. The input is used to change blade position as well as navigate the machine.

the appropriate type of output (**FIGURE 21-12**). When a change is made, the sensing system will observe the new data and provide feedback to the processing system about whether the change is accurately following the direction given by the decision-making system. This process where the operation of an output device is monitored by a sensor is called **closed-loop control** or closed-loop feedback (**FIGURE 21-13**). If the system actuator's response is not correct, the sensing system provides the feedback to the decision-making system to make further corrections or supply a different output signal or message.

► Enabling Technologies for Machine Automation

K21004, S21001

Composing the elements of automated machine system architecture is another layer of technologies that are selected, arranged, integrated, and synchronized to form the whole

FIGURE 21-12 This electric-over-hydraulic control valve manifold interfaces with a CAN-controlled electronic module. Signals from the CAN network, including remote signals, will actuate any type of hydraulic controls.

automated machine. A detailed description of each of the following technologies common to most automated machines forms the scaffolding used to build machine architecture. This more fundamental layer of technology forming machine architecture includes the following networks.

Onboard Networks

Onboard machine networks are formed by connecting various machine electronic control modules to communicate and exchange information (**FIGURE 21-14**). One of the primary reasons for first constructing onboard networks is to reduce the need for complex wiring and redundant sensors. Sensor data collected by individual modules can be shared across a large number of devices connected into a network. This network feature eliminates the duplication of sensor input and associated wiring supplying each module needing the data. Connecting the

FIGURE 21-13 Principle of closed-loop feedback. A sensor will measure an actuator or output pressure or position. The engine control module (ECM) makes adjustments to the actuator to correct any deviation from commanded position or pressure.

FIGURE 21-14 Multiple electronic control units are connected with a pair of wires to form an onboard machine network.

FIGURE 21-15 Communication principles of time division signal multiplexing over an onboard network. To prevent signal collisions, one module transmits information at a time while the others listen.

modules together using a pair of wires common to all the modules also eliminates the need for point-to-point wiring. The pair of wires called the data bus operates like a party line telephone system (**FIGURE 21-15**). A simple example of how onboard networks simplify electrical system wiring and sensor redundancy is the use of an engine speed sensor. These data are required in many places by various devices, such as the instrument gauge cluster, transmission, hydraulic control system, and other modules. The transmission needs it to calculate shift schedules and the hydraulic control system to match engine speed with hydraulic loads. Using one electronic control module to sense and process speed sensor data and then distribute the information over the network reduces the construction cost and associated wiring required to connect an engine speed sensor to each module requiring speed data. Note too that the information-processing capabilities are distributed over many modules, which enhances the power of the total network. Instead of numerous modules performing the same task—such as processing speed data—one module alone does it, which frees the processors in other ECMs to perform work.

The idea of “the whole being greater than the sum of its parts” applies to vehicle networks. Connecting modules together to share information makes it possible to customize many additional operational features. This idea of a vehicle

network is somewhat similar to social networks, where people are connected through websites or organizations to exchange information and even collaborate to accomplish tasks or reach goals otherwise unachievable when unconnected. Extensive use of microprocessor-based controls applied to nearly every machine system can also be leveraged using network communication to provide a huge number of benefits not possible with modules and devices left unconnected.

Information is digitally communicated across onboard networks by using a series of 1s and 0s, representing numbers and letters. Each module transmits a 0 or 1 using a brief positive and negative voltage pulse. However, if voltage pulses were simultaneously transmitted together over a single wire pair, the voltage representation of 0s and 1s would collide and cancel out one another. Information would become garbled, a lot like a noisy classroom when everyone is speaking at once and no one is understood. To prevent this, an electrical signal communication strategy called multiplexing overcomes the problem of signal collision and cancellation. **Multiplexing** simply refers to a concept where the transmission of more than one electrical signal or message takes place over a single wire or pair of wires. In current models of machines, thousands of messages are exchanged every second over onboard networks using serial data—that is, data consisting of 1s and 0s sent one after another in series,

transmitted by various control modules. Multiplexing used by onboard networks works by dividing the time available to each network module or device to transmit and listen to information. Time division multiplexing (TDM) requires the modules and other devices take turns sharing the communication pathway. Only one module is allowed to talk and all other modules must listen until it is their turn to talk. This is like a well-ordered classroom where there is cooperation around communication and the rule is no one interrupts someone else until they are finished speaking. Data transfer back and forth along the data bus does not take place simultaneously but each device transmits and receives data by cooperating to time-share a common signal path. The speed at which the data exchange takes place makes communication appear to take place simultaneously but it is in fact not.

Time division multiplexed communication strategy is not unlike Morse code using a sequence of dots and dashes to represent any letter or number combination. The biggest difference between the serial data of on board networks and Morse code is the speed the data is exchanged. Modules communicate much faster than old Morse code through the use of microprocessor electronics.

Controller Area Networks

The term “controlled area networks (CAN)” describes a distributed type of network communication control system. This means that no single central control module is used on a machine. Instead, each module or node on the network has processing capabilities that can not only initiate electrical control for faster response but also synchronize their operation with other network modules. This means each module on the network has memorized the rules of what it has to do and the rules for doing it. Because the network has no central control, parts of it can be severed and the connected components will still operate. CANs are the most widely used type of network used to integrate all operations of all the latest machines. CAN networks are often integrated in local area networks (LANs), a term which refers to a vehicle having multiple types of networks, such as optical or proprietary networks connecting manufacturer-specific equipment. Since there is no central control module coordinating communication or controlling network devices, each network module has built-in processor capabilities to process input and output data while simultaneously receiving and transmitting data to the network. A built-in clock and transceiver in each CAN module helps synchronize multiplex communication between modules so that each takes an appropriate turn using the data bus to send and receive messages. Other processing functions built into every CAN module allow it to interpret other network communication data and control what messages it sends to the data bus.

The CANbus

Electronic control modules can be connected in a variety of ways. **Network topology** refers to a term describing how modules are connected to one another. Most often, the topology refers to a physical shape of the way a network is connected (**FIGURE 21-16**).

FIGURE 21-16 Network topology refers to the shape of the connections formed between network modules.

A star network’s interconnections are shaped just like that—a star. Ring and bus networks are other common shapes or layouts of connection configurations for the channel’s exchanging data. The term “CANbus” when used in network topology describes network connection that look just like a bus route on a street with two lanes for traffic. The street also has bus routes and bus stops along the way, which are electronic control modules.

Since there is only one path for electrical signals to travel on the CANbus—that is, one street—data are transmitted one bit at a time, one after another, or in series. A positive voltage of anywhere between 2 and 8 volts in comparison to a pulse of lower voltage would represent a “1.” No voltage on either wire is “0.” Voltage on the paired wires is a mirror opposite to achieve a sharp crisp differential voltage that is easily understood by the modules (**FIGURE 21-17**). Using differential voltage and twisting the wires minimize electromagnetic interference (EMI) in the wires, also called electrical noise, in wiring carrying serial data.

One wire is called CAN-H, which has a more positive voltage than the other, which is called CAN-L. Each wire will have a mirror opposite charge or polarity of the other when communication takes place. The **differential voltage** provides the best method for transmitting signals without noise.

Differences Between J-1939-2 CAN and ISO 11783 CAN Networks

There are a number of CAN networks used by off-road machinery, which differ primarily according to the rules, also called protocols, used to transmit and receive messages. A network layer is a term used to describe the ways these protocols organize sets of rules together. For example, protocol layers set rules for constructing connectors, how many modules can be connected, how far they can be separated, how fast messages should be transmitted, what diagnostic information should look like, etc. For off-road machines, three protocols are primarily used. One protocol primarily for machines built in North America is the SAE-developed **J-1939-2** network used by agricultural and forestry vehicles, and the **J-1939** network

FIGURE 21-17 Principle of differential voltage transmission. A series of 1's and 0's is transmitted over the data bus contains digital information.

for off-road HD commercial vehicles uses a bus-type typology. The other is **ISO11783** series, also called an ISO-bus, developed in Germany and used primarily by European agriculture and forestry machines. All three standards—J-1939, J-1939-2, and ISO11783—are international standards and similar in defining the methods and protocols for data transfer between sensors, actuators, and control modules, as well as information storage and display units regardless of whether they are mounted on the machine or on implements. The J-1939-2 and ISO11783 are serial data network protocols that prescribe communication standards for forestry or agricultural tractors

and mounted, semi-mounted, towed, or self-propelled implements such as cultivators, sprayers or harvesting machines. The data link connector is the easiest way to distinguish between each network. J-1939 uses a 9-pin connector, while ISO has a unique combination of power ground and data bus connectors (**FIGURE 21-18** and **FIGURE 21-19**).

Several features are unique to ISO11783. One is the provision for the addition of a **virtual terminal** in the cab of a machine (**FIGURE 21-20**). The virtual terminal is a screen mounted in the tractor used to allow the operator to control connected implements. Modules on ISO-bus machines can

FIGURE 21-18 The configuration of the ISO 11783 data link connector.

FIGURE 21-19 A J-1939 data link connector.

FIGURE 21-20 A virtual terminal in the cab of a machine displays information transmitted over the CAN.

transmit what are called virtual objects along the CANbus to be displayed on the virtual terminal. The objects are visual representations of the implement or device controlled by the module. Multiple implements can be displayed on a single screen, which makes the use of the virtual terminal important in agricultural applications since it eliminates any separate implement control unit or its wiring unnecessary; one terminal allows the operator to control all of the implements. The J-1939-2 standard has similar capabilities but is less sophisticated in its support of the virtual terminal than the ISO-bus.

Telematics Standards

Other important additions to the ISO-bus standard include enabling the use of standardized telematics across all manufacturers. The interoperability of devices used on various OEM CAN networks is important to supporting customers by

delivering basic telematics data in a standard format. Without this standardization, companies with mixed fleets of machines made by Cat, Komatsu, or Deere would need to use a separate provider to analyze telematics data. Extensible markup language (XML), a programming language used by ISO-bus that defines a set of rules for coding documents in a format that is both human readable and machine readable, is a differentiating feature of ISO 11783 from J-1939.

► Global Positioning Systems

K21006

The GPS, also called the **global navigation satellite system (GNSS)**, is a worldwide radio-navigation system that has had a tremendous impact on the advancement of automated machine guidance and navigation. To carry out precision-farming techniques or have machines operate on a construction site to dig, shape, and grade surfaces, precise machine positions that are accurate to fractions of an inch are necessary. GPS has provided this capability since the mid-1990s, when the navigation system built originally in the 1970s for the American military was opened up to civilian use. Several other GPS systems are operated by other nations and used by machines in North America and around the world. For example, Russia has a system called GLONASS; Europe has the Galileo System; Japan has the Quasi-Zenith Satellite System (QZSS); and China has the Compass System. Each system's fundamental operational concepts are the same but have slightly unique position-sensing advantages for equipment depending on where it is located. But most GPS systems on today's machines use dual frequency receivers receiving two GPS signals. When referenced together, the signals are integrated and the accuracy of each system is significantly enhanced.

Identifying Global Positions

Inexpensive GPS receivers, which are often integrated into the onboard network, are essential for any application requiring navigation or position-sensing capabilities. In North America, the GPS system consists of a constellation of 30 satellites orbiting the earth with 24 or more satellites visible to receivers on earth (**FIGURE 21-21**). To identify any position on earth, a GPS receiver needs to receive signals from three or more of these satellites. To do this, a mathematical concept called **triangulation** is used. Triangulation works when a receiver connects with signals transmitted from each satellite at precisely the same time. Since the satellites are located at different distances from the receiver, the signals will arrive at slightly different times (**FIGURE 21-22**). A time stamp on each signal allows the receiver to calculate how far it is from each satellite. By subtracting the time the signal was transmitted from the time it was received, the GPS receiver can measure the distance between it and each satellite. If the GPS receiver also knows the exact position of the satellites when the signals are transmitted, the intersection point of signals form a three-dimensional (3D) position with calculated coordinates indicating how far east or west (longitude) and north or south (latitude) the receiver is from the

FIGURE 21-21 GPS, or global positioning system, is a generic term for satellite-based communication, which can be used for identifying machine position and navigation.

satellite. Additionally, the altitude or height above sea level of the receiver is calculated. Without signals from at least three different satellites, significant error has to be factored into the receiver's location (**FIGURE 21-23**). For example, if the receiver is located at a high altitude and three signals are not received, the receiver may use sea level as a reference point for location and locate the receiver a distance at least equal to the altitude away from the actual location.

GPS Signal Information

Note that the receiver needs to determine the location of the GPS satellites to calculate a position relative to the satellites. Two types of satellite data are required by the GPS receiver: the almanac and the ephemeris. The almanac and ephemeris contain information about the orbital information and location of the satellites. Both sets of data are transmitted intermittently by the GPS satellites, which are collected and stored by the GPS receiver. Unfortunately, this information is not continuously updated, and the receiver may need as long as 15 minutes to update almanac data and two hours for ephemeris information. Without the information, the receiver cannot accurately locate a position, which explains why sometimes it takes a long time to initially start up a GPS receiver.

FIGURE 21-22 A GPS receiver can accurately measure the distance to each satellite based on signal transmission time.

FIGURE 21-23 Triangulation—the use of three different angles to estimate position—is used to geo-locate a machine.

The terms “hot start” and “cold start” when used in relation to GPS devices refer to whether the receiver has recent almanac and ephemeris information. If the most recent information is not available, it is a cold-start condition. Assisted GPS or A-GPS used by cell phones will collect the almanac and ephemeris data more quickly from computer servers connected to the Internet rather than from satellite transmissions.

GPS Signal Correction Systems

Conventional GPS data can provide positional accuracy to within 10 m. Disturbances in the atmosphere, accuracy of GPS clocks, and satellite data can skew accurate positioning. To correct this problem and provide precise location, GPS units will

have signals corrected using at least one of several supplemental ground-based reference stations. When the precise position of a ground station is known, data from ground reference stations are transmitted to the GPS receiver in order to apply a correction factor. These supplemental correction systems are needed to obtain positional accuracy to less than $\frac{1}{2}$ inch or 1.27 cm for CAESs or machinery operating in farm fields navigating between rows with similar positional accuracy. Differential global positioning system (DGPS) wide-area augmentation system (WASS), **real-time kinematic (RTK)**, and dual frequency receivers are terms used to categorize supplemental GPS technology to correct satellite GPS error. These systems are privately owned but provide satellite differential correction subscription services used to improved positional accuracy to the decimeter or less than $\frac{1}{2}$ inch (**FIGURE 21-24**).

On jobsites where equipment uses GPS to guide and control precision grading or asphalt paving, a radio base station or two supplemental rover devices help correct the GPS signal supplied to machine controllers. These generally provide even more precision for the geometry needed to accurately measure vertical dimensions. A GPS base station that receives satellite signals makes any necessary corrections to satellite signals and then transmits the corrections factors to GPS receivers on machines. Using the base station to correct satellite signal error, machines can operate from 6 to 9 miles away and maintain reception of the base station’s signals.

GPS and GNSS Application

When considering applications for GPS, the first association is to a cell phone map app or a navigation system integrated into the dash of a car’s or a truck’s media system, providing the driver

Machine Control to Control Absolute Position

3D Machine Control System (GNSS)

FIGURE 21-24 Satellite GPS requires assistance to more precisely locate machine implements and blades using a correction factor supplied by fixed point, land-based signals system.

with turn-by-turn directions. However, GPS has turned into an extremely valuable technology for off-road equipment.

GPS is used to locate and track equipment. A compact GPS receiver and radio transmitter tracking device can be connected into the onboard network and recognized like any other module. After that, it can then be used to locate the equipment and plan route activity. Since theft is a bigger concern with off-road equipment because it is often easier to steal than on-road vehicles and is far more expensive to replace, GPS can provide **geofencing** capabilities. With geofencing, a manager can be alerted to the movement of a machine outside a particular geographical area or expected operating hours. The same module can provide telematics data to a service provider, where machine data and statistics can be easily viewed on a website even though the equipment is half way around the world.

In most instances, the GPS device will use the equipment's battery current, but it can be configured to use its own internal power source that can last up to seven years. The device will transmit status updates when certain events, such as starting the engine, are triggered—as well as location updates at regular intervals, which are normally every two minutes.

CAESs are GPS-based earth-moving equipment that can use satellite data to compute the positions of machines, blades, and implements by using GPS antennas mounted on equipment. Project-specific design information stored in an onboard computer is used to compare the precise position of the earth-mover's blade, boom, stick, shovels or buckets against site-design coordinates. Machine operation is controlled according to a stored 3D map in order to cut, fill, or dig to a profile that exactly matches the X-Y-Z coordinates on a digital topographic plan. This eliminates the requirement to survey and stake a site and resurvey to measure progress.

The big players in the 3D GPS grade-control market are Topcon, Trimble, and Leica Geosystems.

Indicate and Automatic Mode

Machines equipped with GPS/GNSS have two options when using satellite positioning. One is indicate mode, which uses data produced during machine operation to provide the feedback to the operator who controls blades, shovels, or implements control. During **indicate-only mode**, the final contours of the work site are displayed on the cab terminal screen. When grading, the operator has to manually adjust the elevation and slope of the blade to match the plan, and the GPS only provides the operator with feedback about grading or digging information on a cab terminal (**FIGURE 21-25**).

In the second option or fully **automatic mode**, the machine's hydraulics are electronically controlled with no driver intervention make blade or implement adjustments. Most GPS guidance systems also provide the operator with the ability to define a specific grade elevation or grade angle without a specific design.

GPS Hydraulic Interface

A fully automatic CAES requires the GPS guidance system to be integrated into the machine's hydraulic implement controls. OEMs currently produce machines with these controls already

FIGURE 21-25 This GPS CAN logging module connects satellite communication to a machine's CAN network supplying GPS data to the CAN network.

built in as an option. Aftermarket retrofit kits are also available, which enable the conversion of a machine into a fully automatic control. To interface or connect the GPS to the machine's implement controls, one of two methods may be used. The first is relatively simple if the machine is built using electric-over-hydraulic (EH) implement controls. In this instance, the GPS system can supply an input lever with electrical signals connected in parallel with the machine's implement lever. The signal from the retrofit GPS control module interprets the electrical signals as a lever command supplied by the operator and moves the hydraulic control accordingly. The second method for integrating GPS in the machine's hydraulic system on older or simpler designs is by adding a second pilot hydraulic valve in parallel with the machine's pilot hydraulic valve. This second valve is controlled by or integrated with data from the GPS CAN module and moves the hydraulic valve, thereby regulating the implement according to programmed instructions and feedback from the blade, bucket, or implement position supplied by sensors or GPS devices (**FIGURE 21-26**).

Blade and Implement Positioning Systems

To provide an adequate set of data to the GPS's CAES blade, bucket, or implement position, it needs to provide feedback to the GPS control module. This is accomplished in several ways.

1. Installation of at least one GPS antenna/receiver mounted on the machine's blade. The machine will also have a GPS receiver and a radio. This enables the operators to use an indicate-only system to view two-dimensional (2D) site cross sections, elevations, and blade position diagrams. The

FIGURE 21-26 **A.** An electronic control module connected to the CAN network can operate pilot control valves in this hydraulic manifold. **B.** A control valve manifold assembly having electronically controlled pilot valves paralleling lever controlled valves.

machine's location relative to the site can also be mapped. However, side-to-side blade position is not precisely indicated. Machine position is determined, but not its orientation on the jobsite. However, a separate angle sensor can be incorporated into the machine to calculate the machine's slope. Furthermore, the accuracy of this system is dependent on the use of a site base station to provide correction factors. When a base station is used, the accuracy of an indicate-only system improves to approximately within 2–3 cm (**FIGURE 21-27**).

2. Installation of two GPS receivers on the top of masts of a blade or implement provides an accurate 3D, left-right, horizontal and vertical position of the blade. Using only one GPS receiver limits how the guidance system can sense the machine's position relative to the site design. Using two GPS receivers supplies the guidance system with two points of position, allowing it to calculate what angle the machine is on relative to the site plan. The GPS receivers allow the system to measure the machine's blade location within 1–2 cm accuracy for precise blade control and machine guidance. When grading, cross-slope information on steep slopes is provided even in high vibration environments. The front-to-back and side-to-side position of the machine can be integrated into tracking and guidance software (**FIGURE 21-28**).
3. **Inertial measurement systems** where **inertial measurement unit (IMU) sensors** are attached to the body of the machine, blade, or implement. When attached to the machine body, the positioning or spatial data as well as the known dimensions of the machine, enable the system to precisely calculate the position of a cutting blade at all times. IMUs and software model information provide a precise X-Y-Z position of the blade relative to the design

FIGURE 21-27 The use of one GPS antenna/receiver located on a machine blade provides 2D data.

FIGURE 21-28 Dual GPS antennas not only identify bucket and blade position but a machine's centerline in relation to 3D site maps.

FIGURE 21-29 An inertial mass unit senses machine, implement boom or stick movement which is wirelessly transmitted to a control unit.

surface. IMUs communicate with each other as much as 100 times a second to provide a faster 3D mapping and machine response. Machines using IMUs are commonly referred to as “mast-less” GPS/GNSS systems (global navigation system) (**FIGURE 21-29**). However, IMUs will transmit information to the CAN, where it is integrated into the machine control system operating hydraulics and navigation or positioning systems.

4. Since GPS masts on the boom and stick are not practical, excavators use GPS technology along with **rotating ring laser angle sensors** integrated into the machine's boom, stick, and bucket. These sensors are a variety of IMU sensors and generally combine a ring-shaped arrangement of a laser with mirrors and a specialized laser light sensor or catcher that detects movement. Laser IMUs are sophisticated optical sensing devices that use a laser, two mirrors, and photo diodes that depend on principles of light diffusion (shifts from red to blue wavelengths) to detect speed and direction of movement. Data from these IMU sensor setups allow the operator to see how deeply they are digging and compare the actual bucket location to 3D topographical site

designs on the cab terminal GPS display. Semi-automatic excavators will allow the machine to automatically raise the bucket to maintain the predetermined hole depth and will have an autostop function to prevent the bucket and boom function from lower beyond the predetermined hole depth (**FIGURE 21-30**).

5. Three **light bars** mounted in the machine cab of earth-moving machines can provide vertical and horizontal indicate-only guidance to the operator. Bright green indicates “on grade,” and amber indicates “above” or “below” grade. In agriculture tractors, light bars can help a tractor steer between rows of crops accurately to prevent over-spraying or seeding errors.

► TECHNICIAN TIP

The two most common failure points on GPS systems are (1) the cables connecting GPS antennas to control modules and (2) cab terminals that are improperly sealed, allowing water, dirt, and other elements into the units. Units are equipped with onboard diagnostic systems to identify problems. But since GPS antennas are expensive and prone to theft, most operators remove the antennas at the end of a shift to prevent theft. This situation creates significantly more wear and tear on coaxial cables connections to the units. To reduce downtime, spare antenna cables are commonly kept in stock, and terminal connections should receive a light coating of dielectric grease to prevent corrosion.

GPS System Limitations

While GPS systems can boost productivity by 30% or more, the acquisition cost on a large new machine equipped from the factory can be \$100,000 per machine. Retrofit GPS systems are available for lower costs on some machines and are transferrable from machine to machine. GPS cannot alone enable fully autonomous machine navigation and must be supplemented with other sensing systems.

When used, the GPS unit must have an unobstructed site line through the sky to satellites in order for signals to reach the antenna. This means GPS will not work underground or in street canyons where buildings obstruct signals. At high altitudes and latitudes, the satellite signals can weaken due to the orbital pathways used by satellites. The Russian-built GLONASS system using satellites located higher above the earth, which provides better coverage in these circumstances.

Strong electromagnetic waves can interfere with GPS signals as well. Unusual solar activity or high-voltage power lines, for example, can block satellite signals if machinery is operating beneath power lines.

Radar

Radar is an acronym for radio detection and ranging. It is a familiar technology with many applications that not only detects objects but also determines their distance, angle, and velocity relative to the radio transmitter. Just as light can be absorbed or reflected from the surface of an object to make it visible, radar uses electromagnetic waves reflected from an

FIGURE 21-30 Laser sensors on the boom and stick provide precise machine coordinates for topographical 3D excavating.

object to make it visible to a radio receiver. A typical radar system will act as a transmitter and receiver of radio waves by sending pulses of radio waves for a few milliseconds and then stopping to listen for reflections of radio waves from an object. The radio receiver and signal processor analyzing the reflected radio waves can determine properties of the object, such as whether it is soft like a human being or hard like concrete. The time it takes for bounced signals to reach the receiver will provide information about the object's location and speed relative to the radar (**FIGURE 21-31**). A common application for simple radar devices is to measure ground speed (**FIGURE 21-32**).

Radar is preferred in guidance and navigation systems because it's computationally lighter than a camera and uses far less data than a **lidar** (radar using light detection principles). That means that comparatively less powerful computers are required to process and interpret the information from the radar. While radar signals are less accurate than others at detecting an object's position, radar can work better in more difficult conditions, such as in snow, rain, fog, and darkness. Additionally, various levels of automation will depend on radar to "cross-validate" or double-check what other sensors are seeing in order

to predict motion or an object's properties. For example, a green tarp spread on a field or over the ground may be recognized by a camera as grass or a hazard to avoid. Radar, however, can differentiate the object from grass by characteristics of the signal that bounce off the tarp. Furthermore, when a tarp covers a hole or piece of equipment, the radar has the capability to see around or below the tarp.

Lidar

A new sensor technology often used in conjunction with radar is lidar. Lidar is an acronym for light detection and ranging, using pulsed laser beams rather than radio waves to measure distances. Using ultraviolet, visible, or near infrared light, it scans the environment to image a wide range of materials and objects. Metal, rocks, rain, chemical compounds, aerosols, and even clouds are scanned, and 3D images are produced by lidar. When combined with other data from radar, cameras, and GPS, high-resolution images containing enormous amounts of data can be used to navigate a machine as well as provide input to any other automated activity.

A lidar instrument consists principally of a laser redirected with a rotating mirror, which is used to scan the surrounding

FIGURE 21-31 Radar and sonar calculate distance and speed based on the time difference between a wave emission and reflection.

FIGURE 21-32 The four-to-one radar adapter allows one radar velocity sensor to provide a ground speed signal for a maximum of four separate devices, such as a control system, an instrument package, spreader, and a planter monitor.

environment. It is accompanied by a light-detecting receiver or scanner. A pair of lasers that beam light from the instrument through a mirror directs the beams at different angles to form a wide field of view called a layer. Each layer of a lidar is called a channel, and the signal from each individual channel creates a

contour line. The rapidly rotating lidar mirror scans a 3D image of the surrounding environment from the contour line, much like an optical scanner. Adding more layers to a lidar improves its resolution, and many of today's lidars are produced with 16, 32, and 64 laser channels.

Lidar is currently an expensive technology: a 16-channel product costs close to \$8,000. Adding multiple lidars to a machine makes the system even more costly to acquire. However, one collision avoidance systems application currently used by Volvo construction equipment uses a two-channel lidar and combines the data with three RGB (red, green, and blue) cameras. A terminal screen inside the cab provides the operator with a display showing the machine's location and the presence of other machines and pedestrians. If **RFID (radio frequency identification)** tags are embedded in the vests of workers, the cab terminal flashes and broadcasts a warning sound from the direction where a potential collision is detected.

When GPS signals are lost due to obstructions, the lidar can be used to guide a machine until the signals is re-established. Lidar sensors can also detect the edges of crop rows and distinguish crops from weeds and other foliage, which has great value for object detection systems.

Computer Stereo Vision

A machine's perception system needs to identify objects as well as gauge their speed and direction. To avoid the problem of producing what are called false negative detection (blindness to an object) and false positive detection (nonexistent ghost objects), more than one object sensing system should be used. Cameras provide a good method to cross-check or validate data from other sensors to prevent a catastrophe if a dangerous obstacle is not detected. Cameras are also relatively inexpensive. And unlike lidar, which see just gray scale images, cameras can see color that helps accurately classify or identify an object. This means cameras can see hazard flashers, clearance lights, brake lights, turn signals, and any other light on other vehicles. For reading road signage, a camera detecting red, green, and blue (RGB) is the best technology. In order to measure distance, two cameras or **stereo cameras** are necessary.

There are several drawbacks to camera technology. One is the difficulty of processing the amount of information produced by a camera that uses software. Cameras are computationally intensive. Lighting variations, such as when objects move into a shadow, can confuse cameras as well. This means they should have additional lighting to work well and not rely on just reflected light sources (**FIGURE 21-33**).

FIGURE 21-33 A schematic view of processing functions using color cameras integrated with an automated navigating system.

Two cameras providing binocular vision are required to measure depth or provide stereo vision using the principle of parallax. With parallax estimates, the shift in location of an object as seen between two different camera angles enables the calculation of a precise distance of an object from the cameras. Cameras can supply not just images but also software that can perform two basic types of analysis of the data. One is machine vision, which refers to a simple analysis of digital images to identify features, edges, detect motion, and motion parallax, depends on two cameras or binocular images to estimate distance. A tomato-picking robot uses edge, shape, and color information to locate the tomato and stereo vision for depth.

Another capability provided by binocular camera vision is computer vision. **Computer vision** refers a more difficult challenge of recognizing and interpreting the significance of objects. For example, differentiating between a human and a lamp post is more difficult than simply locating the two different objects. Even more difficult is discerning where the human's attention is and whether they are walking into a machine's path.

Radio Frequency Identification

While not directly integrated into automated machine technology, radio frequency identification (RFID) technology is used on the connected machine and work site. Tags are typically attached to equipment as part of an inventory tracking system and can be associated with telematics data. Safety systems used on machinery can sense RFID tags attached to worker clothing and can be used to alert a machine to the proximity to a worker.

RFID technology uses electromagnetic fields to automatically identify and track objects attached to tags. Information about the object, such as a blade or machine, is electronically stored on the tag and can be read by an RFID reader. RFID technology can be classified into two basic types—passive and active. Passive tags are powered as they collect energy from a nearby RFID reader's radio wave emissions. The RFID tag reader will ask the tag to supply information using radio signals containing electromagnetic energy to interrogate the tag. This energy is used to power up the tag and supply data to the reader. To work, then, a passive RFID must receive a radio signal with a power level approximately a thousand times stronger than that used for signal transmission. Naturally, these tags have an effective working range of just 3 feet and are susceptible to electromagnetic interference. However, newer tags using ultra-high-frequency signal readers are reported to operate up to 80 feet. A subset of RFID passive technology is seen in credit cards using near field communication chips (NFC). These cards contain a more secure type of RFID technology, but the principles are identical.

Active tags have an internal power supply, such as a battery, and can operate at hundreds of meters from the RFID reader. Unlike a passive RFID tag, an active RFID periodically transmits an identification signal. Bluetooth devices and Internet routers can read data from active tags. These types of tags do require battery replace from time to time (**FIGURE 21-34**).

RFID active tags can be simple, costing just a few cents, or more complex devices. The tag requires an integrated circuit for collecting and processing information, plus radio circuits

FIGURE 21-34 Inside an active type RFID tag.

FIGURE 21-35 An RFID tag attached to a machine blade used to identify equipment.

for receiving and transmitting radio signals. To collect DC power from a tag reader signal, passive tags will temporarily store DC current too. RFID tag memory can be either fixed with only a factory-assigned serial number or programmable memory that has a read/write capability. Specific equipment or object data can be written to the programmable RFID tag (**FIGURE 21-35**).

► Telematics

K21005

The term telematics is a combination of telecommunications and informatics—the science of processing data for storage and retrieval. Telematics is a technology field encompassing wireless

communication, telecommunications, machine technology, onboard networks, and the use of the Internet. Essentially, it collects information from a machine or piece of equipment and sends it to a website, where it can be viewed and analyzed. Telematics systems installed on machines typically combine GPS technology with a communication connection to the onboard network to locate the machine, monitor its operation, and log and report data through Wi-Fi or cellular networks. A set of data from telematics systems is typically accessed through a subscription-based website providing data on one or more machines made by different original equipment manufacturers (OEMs). Equipment manufacturers are installing telematics systems as standard equipment on an increasing number of their products each year.

Common data points include

- GPS location
- fuel consumption
- idle time
- fault codes and warning messages for remote diagnostics
- engine hours
- route activity
- driving behavior
- vehicle utilization
- distance.

Using telematics systems to record simple factors such as machine hours and to measure idle time enables equipment managers to maintain preventive maintenance schedules, increase security through GPS location and geofencing, and use geofencing to help allocate machine time costs to a particular jobsite. Far more advanced analytics of machine operation can be achieved by adding additional sensors beyond all the sensor data available to the onboard network.

Until 2010, each OEM had its own unique telematics standard, which meant that a Deere, Cat, or Komatsu telematics provider couldn't provide information to the same owner for other machines in the fleet. The Association of Equipment Management Professionals (AEMP) developed the industry's first telematics standard for off-road heavy equipment. This meant that regardless of the machine brand, its telematics modules could supply equipment data to a single web-based telematics provider. This meant that telematics data wasn't limited to a single brand of machine used with a mixed-brand fleet of other equipment. Caterpillar, Komatsu, Volvo CE, John Deere Construction & Forestry, OEM Data Delivery, Navman Wireless, Topcon, and Trimble are able to deliver basic telematics data in a standard XML format (a programming language used by the Internet).

Telematics Standards

The **AEMP Telematics Data Standard** also provided the end user with the freedom to use one telematics service provider to retrieve data from any other rather than require a unique provider for each brand of machine. Version 1.2 of the standard includes 19 data fields in addition to SAE and ISO-bus fault code reporting capability. Some types of equipment are not yet

covered by the standards, such as some agriculture equipment, cranes, mobile elevating work platforms, air compressors, and other niche products.

Telematics Modules

Telematics equipped machines will use an onboard electronic control module to collect, store, and transmit machine data over cellphone networks. However, most advanced modules have support for other wireless communication options, such as Wi-Fi, classic Bluetooth, and Bluetooth low energy. Both Bluetooth and Wi-Fi can operate concurrently since the modules will internally switch between Bluetooth and Wi-Fi when needed, to prevent any simultaneous radio transmissions. Modules are designed to provide both wired and wireless access to the CAN network of a machine through WLAN/Bluetooth (FIGURE 21-36).

► Remote Control

K21007

Remote controls operating diesel-powered load-haul-dump (LHD) vehicles first appeared in underground mines beginning in the 1970s. Today, they are used on many types of construction equipment in order to enhance operator safety and improve production efficiency. On worksites where the operator may be in potentially more danger due to conditions such as falling debris, steep slopes, or unusually dusty conditions, operators can remove themselves from the machine and operate it at a safer distance. A safer distance may be line of sight, where the operator controls the machine using an alternate duplicate set of controls while watching the machine. For some remote-controlled machines needing to operate beyond the range of line of sight, video cameras can be mounted on the machine to enable the operator to observe what the machine is doing and how it is responding to inputs from remote controls. Since remote controls do not provide an operator with feedback such as hearing and feeling how

FIGURE 21-36 A cellular network combined with Internet connectivity connects to the machine's CAN network to supply telematics suppliers with data.

FIGURE 21-37 A remote-control workstation duplicates machine controls to enable remote operation. Note the seat mechanism, which moves back and forth to provide sensory feedback from the machine.

the engine and hydraulic controls are responding to inputs, advanced use of additional sensors on the machine can be used to record and transfer information to a clean, quiet, climate-controlled remote workstation (FIGURE 21-37). System information such as engine or machine travel speed, system pressure and temperature values, machine and position derived from pitch, and yaw and roll sensors can report orientation. Workstations can use remote-control software so that the operator can view equipment action with a 3D display. Built-in mechanisms in the machine controls can even provide mechanisms for force feedback on acceleration, braking, and the bucket operation to enhance the ability of an operator to work remotely.

Radio Control

Early portable remote-control receiver and transmitter units used coded radio signals to prevent unintentional operation of other equipment or interference from nearby radios transmitters. This meant the radio frequencies of the transmitting and receiving radio had to match to work. The receivers were electrically connected with a machine's electric, hydraulic, or pneumatic systems to control functions such as steering, braking, and load handling. While most systems still depend on radio signals to conduct two-way exchanges of information, the signals are digitized for safety reasons and to exchange more data than analog signals can allow. Digitizing the radio signals enables very secure transmitter/receiver communication, which can tolerate high levels of interference. They also permit bidirectional communication to allow the transmitter to validate correct data transfer between the machine and remote controls. In underground mining, the signals are typically sent over Wi-Fi routers using Internet protocols.

On any jobsite or fleet operation, it's important that remote controls have a standardized configuration in terms of how they control work for forward, reverse, and left and right orientation as well as for emergency stop, fire suppression, and other buttons or joystick controls. Mixing transmitters with a different

FIGURE 21-38 This radio remote-control unit has a large red emergency stop button.

set of controls can lead to errors when operators move between different controls. When the joysticks of a remote console are released, no forward or reverse signals are transmitted and the machine should immediately stop rather than roll on. Controls will use an emergency stop switch that shuts down the machine when it is pushed (**FIGURE 21-38**).

When used by an operator for line of sight, portable transmitters should contain a tilt switch that ensures the transmitter will stop the machine if the operator were to trip and fall. Tilt switches should deactivate the machine when the control held by the operator moves more than 30 degrees or more from level.

Software such as Cat's Command for underground mining is capable of three levels of operational control, which is enhanced with video from onboard cameras to provide a real-time view of the machine location and operation.

Basic or tele-remote mode allows the operator to control the machine through line of sight. In copilot mode, the operator can monitor equipment locations in a mine plan and by using joysticks to give the machine directional input. Onboard perception systems such as radar, combined with radio network infrastructure providing a mine map, enable the machine to self-steer along a safe path. The most advanced element of control, namely autopilot, allows the machine to autonomously dump and return to the operator, who takes over control of the loading process. Zones within the mine operations area can be configured to regulate machine speed and to establish boundaries at required points. At any time, full operator control of the system can be obtained through tele-remote mode.

Converting a machine to remote operation is relatively simple in the latest models. On smaller Cat construction machines, such as skid steers, approximately an hour is required to install Cat's RemoteTask system. With the system—developed in collaboration with TORC Robotics, Inc. (TORC)—the machine can switch from manual to remote mode at the turn of a key switch. The system is transferrable between units.

► Automated Steering

K21007

An automatic guidance system is similar to a manual guidance system, except that the task of steering is done not by the operator but instead by an application-specific computer that operates machine controls by using special algorithms. To engage the system, the operator will commonly push an engagement switch to allow the system to take control, thereby self-navigating or guiding the vehicle along a calculated safe pathway. Manual control is resumed by simply moving the steering wheel, which is sensed by a pressure change in the hydraulic steering circuits. When autosteering is engaged, the steering controller sends signals to the steering system actuators. The machine path is cross-checked for accuracy using an anticipated GPS position for the vehicle's position. A steering angle sensor measures the turning angle of the steerable wheels, to provide closed-loop control to the steering controller (**FIGURE 21-39**).

Typical Components of Modern GPS Automatic Guidance Systems

Vehicle steering actuators such as the manual override detector receive electrical signals from the steering controller. In wheeled machines, the steerable front wheels will change angle or direction. Tracked machines will alter the speed of the tracks and move the machine according to principles of differential steering. Hydraulic actuators are typically linear actuators or proportional electrohydraulic valves mounted in hydraulic manifolds. A sensor integrated into the control valve body is called a **linear voltage differential transformer (LVDT)**. Essentially, the sensor supplies a voltage signal corresponding to a change in length. When proportional electrohydraulic valves are used, the movement of the spool valve is proportional to the amount of electrical current passed through the sensor's armature coils. As electric current flow increases or decreases through the sensor, spool valve movement is sensed, which in turn is used to calculate the change in the direction and rate of flow to an actuator. In hydrostatic drive machines using hydraulic drive motors at each wheel or track final drive, oil flow through proportional hydraulic control valves using LVDT sensors can differentially steer a machine.

Another type of valve used in steering systems is a closed-loop control valve that also uses a LVDT to measure and precisely position a spool valve. When the spool valve position matches a commanded position, it will cause the machine to steer in a particular direction. Using closed-loop spool position control enables very precise and consistent valve positioning relative to the flow of electrical current (**FIGURE 21-40**).

Primarily for safety reasons, steering interface controls use a manual override system to sense when the operator is providing a steering input by moving the steering wheel of the machine. A pressure sensor in the steering load sense line or a flow sensor that monitors flow in or out of the steering control valve will trip the system and disable the automated guidance system. Steering angle sensors mounted directly in the steering

FIGURE 21-39 A functional schematic of a GPS-controlled steering system that includes implement steering through the hitch integrated into the tractor's steering control.

FIGURE 21-40 This electronically controlled servo valve controlling pressure, direction or force uses a dual 2-stage pilot valve with closed-loop feedback of the spool valve. Both the pilot valve and spool valve maintain precise position control using linear voltage differential transformers (LVDTs) located at the right die end of the valves.

column can perform a similar role whenever the steering wheel is moved by the operator.

CAN-Based Steering

Over the last few years, machines are increasingly equipped with steer-by-wire CAN-controlled steering systems. Inputs are supplied not only through the sensors of the steering control module but received from other modules on the machines,

FIGURE 21-41 Eaton's new wireless steering control valve is intended for autonomous machine control. The wireless transceiver is located on the right of the valve block.

such as from implement control modules. These systems have the advantage of not requiring a parallel and redundant hydraulic system to support both manual and automated steering (**FIGURE 21-41**).

Electric Motor-Driven Steering Wheels

Electric motor drive systems that turn the steering wheel use GPS automated guidance strategies. An example of this system is the Trimble EZ-Steer, introduced in 2004. In the Trimble system, the steering shaft in the steering wheel column is turned

FIGURE 21-42 Trimble's EZ-Steer system uses a foam roller on an electric motor to operate the steering wheel.

by a small electric motor. These systems are sometimes called assisted steering systems and have become enormously popular as easy-to-install, retrofit systems (**FIGURE 21-42**).

Installation time is short, because it has few parts and does not require advanced skills. Systems such as EZ-Steer are easily transferred from one machine to another. One drawback of the torque output from an electric motor drive system is that it requires more time to turn a vehicle at a given angle than when using a hydraulic or steer-by-wire system. As a result of a slower turning and correction speed, there is lower accuracy than with hydraulic drive-by-wire systems. Manual override of these systems is achieved by monitoring current flow to the electric motor. Resisting motor direction, such as when the operator grabs the wheel and turns it in another direction, causes the electrical current flow to sharply increase to the motor. In that case, the control module detects this above-normal current flow and disconnects the motor.

Linear Sensors and Smart Cylinders

Linear movement sensors use a variety of technologies to transform length change into a voltage signal. A common approach converting length to voltage is to use a variable-resistance linear potentiometer. One advantage of these types of sensors is that they are typically easier to fasten on the cylinder than steering linkage, which leads to more accurate position measurement. Another variation of linear sensors is the smart cylinder. These cylinders locate the position sensor inside a hydraulic steering cylinder. Replacing a conventional hydraulic linear-actuated cylinder with a smart cylinder enables the use of a voltage signal to provide closed-loop feedback to the controller regarding steering angle (**FIGURE 21-43**).

FIGURE 21-43 An electric linear actuator provides closed-loop feedback regarding steering position.

Terrain Compensation

Terrain compensation is important to autoguidance systems to compensate for the effect that varying terrain altitudes can have on the machine's position as measured by the GPS receiver. The effect of roll can be very significant when the GPS antenna is mounted on the cab roof. If uncorrected, rolling and changes in altitudes can become a major source of steering error.

Error takes place often because GPS coordinates are measured at the roof of the vehicle and not at the ground where work is performed. Working side slopes or when the machine is tilted to the left or right causes an antenna, installed at a height of 3 m (about 9 ft), to translate 1 degree of roll into 5 cm (about 2") at ground level. When terrain compensation correction is applied, the vehicle's roll, yaw, and pitch (also referred to as the vehicle's attitude) can be measured and corrected (**FIGURE 21-44**).

FIGURE 21-44 Yaw pitch and roll interfere with the GPS's capability to accurately sense machine position.

► Machine Safety with Radio and Other Wireless Technology

S21002

Technicians can be expected to install or repair a variety of technologies that use wireless radio communication. When servicing machines, the following guideless are important.

I. Wi-Fi safety

- Do not install a retrofit self-steering or autosteer device on a machine or use automated applications where life depends on the proper (fault-free) operation of the device.
- Do not enable autosteer or other automated applications unless adequate wireless network availability such as WLAN/Bluetooth is available. Failures or malfunctions of the device can lead to erroneous data transmission.
- Never depend entirely on wireless devices for essential communications, because data transmission cannot be guaranteed at all times and under all conditions.
- Do not use wireless devices in safety-related applications, since most devices that operate using radio signals are not approved for use in safety-related applications.
- Do not operate a wireless device until systems are checked for conformity with legal requirements.
- Wireless devices must not be allowed to operate until after qualified technicians and electricians with advanced knowledge of vehicle and CAN electrical systems have inspected them.

2. Antenna safety—dangers due to absorption of radio frequency (RF) energy

Mobile communication devices may pose a health risk when operated in the close proximity of an operator. Energy in the radio waves is suspected of producing negative impacts on human health. The following lists some precautions to exercise during equipment retrofits:

- Install the antenna(s) used for wireless devices, to provide a separation distance of at least 20 cm (8") from all persons.
- Do not operate wireless devices in conjunction with and do not co-locate them with any other antenna or transmitter.

3. Electronic equipment interference

Electronic equipment can cause dangerous interference from RF energy. Wireless devices receive and transmit RF energy when switched on. Interference can occur if they are used near to TV sets, radios, computers, or equipment that is inadequately shielded from RF energy. Follow any special regulations, and always switch off the wireless unit wherever it is forbidden to use (i.e., during blasting operations) or when you suspect that it may cause interference or damage.

4. Machine wiring guidelines

- To protect wiring installation and other electrical wiring harnesses from mechanical abuse, run wires in flexible metal or plastic conduits.
- Use wire rated for 85°C (185°F), with abrasion-resistant insulation, whereas wire rated for 105°C (221°F) should be used near hot surfaces.
- Use a wire size that is appropriate for the current capacity of the module connector.
- Separate high-current wires, such as solenoids, lights, alternators, or fuel pumps, from sensor and other induction-sensitive input wires.
- Run wires along the inside of, or close to, metal machine surfaces where possible. This provides an EMI/RFI shield that minimizes the effects of electromagnetic interference.
- Do not run wires near sharp metal corners. Use rubberized grommets to protect wiring routed around sharp bends and corners.
- Do not run wires near hot machine members.
- Provide strain relief for all wires.
- Avoid running wires near moving or vibrating components.
- Ground electronic modules to a dedicated conductor of sufficient size that is connected directly to the battery (-).

► Wrap-Up

Ready for Review

- ▶ Automation, which is the use of control systems that reduce or eliminate human intervention to operate machinery, is a rapidly evolving technology sector that has made its way into the off-road equipment industry.
- ▶ Farm tractors, mine trucks, and bulldozers with fully autonomous control systems have been on the market since 2013.
- ▶ Mining equipment has used remote-control systems where an operator can use a set of radio controls that electronically duplicate actual machine controls, enabling operators to work at a distance and avoid potentially hazardous worksite conditions.
- ▶ Smart-iron refers to off-road equipment that integrates some level of telematic, semi-autonomous, or fully autonomous machine control.
- ▶ Automating machine steering, navigation, positioning, object avoidance, implement control, or any driving function can also increase worker and site safety, extend machine durability, and provide a wealth of features and data to equipment managers. Any degree of automation can allow the operator to pay more attention to complex machine tasks.
- ▶ Machine automation doesn't always imply fully autonomous operation. Instead, it refers to varying degrees of machine operation performed without human intervention.
- ▶ Telematically connected machines can transmit machine data collected from the onboard CAN, where it can be collected, analyzed, and viewed through an Internet portal. Data are typically transmitted via the Internet or cell phone signals and includes any measurable information on the machine, such as GPS data, fault information, and data from engines, powertrains, work implements, and hydraulic system controls.
- ▶ Onboard machine networks are important for enabling technology for autonomous machine operation. Onboard networks are formed by connecting various machine electronic control modules to communicate and exchange information.
- ▶ One of the primary reasons for constructing onboard networks is to reduce the need for complex wiring and redundant sensors. Sensor data collected by individual modules can be shared across a large number of devices connected into a network.
- ▶ Onboard networks enhance machine engine control unit (ECU) information-processing capabilities that are distributed over many modules, which enhances the power of the total network. Instead of numerous modules performing the same task—such as processing speed data—one module does it, which frees the processors in other ECMs to perform work.
- ▶ The SAE and ISO have established standards for onboard network design and function. While both standards are similar in operation, they use different data link connectors, software, and communication protocols.
- ▶ GPS systems use satellites to accurately identify the position of a machine. More precise locations of implements, blades, booms, and machine sticks require a land-based fixed location signal to correct error in GPS signals that are derived only from satellites. The signal correction generally requires a subscription from a signal or telematics service provider.
- ▶ GPS units must have unobstructed site lines through the sky to satellites for signals to reach the antenna. This means that GPS will not work underground or in street canyons where buildings obstruct signals.
- ▶ GPS modules connected to the CAN enable machine systems to integrate GPS data into machine hydraulic control, steering, and navigation functions.
- ▶ Autonomous control systems used by off-road equipment include varying levels of technology and operating strategies:
 - remote control (RC) using line-of-site radio signals
 - telematics or tele-operated control
 - self-steering control
 - self-steering + GPS navigation self-navigation + object avoidance system
 - platooning—machine-to-machine communication.
- ▶ Machines equipped with GPS/GNSS have two options when using satellite positioning. One is indicate mode, which uses data produced during machine operation to provide the feedback to the operator who controls blades, shovels, or implements control. In the second option, or fully automatic mode, the machine's hydraulics are electronically controlled with no driver intervention to make blade or implement adjustments.
- ▶ Installation of one GPS antenna mounted on the machine's blade enables the operator to use an indicate-only system to view site cross sections in 2D, elevations, and blade position diagrams. Machine position is determined, but not its orientation on the jobsite.
- ▶ Installation of 2 GPS receivers on the top of masts of a blade or implement provides an accurate 3D, left-right, horizontal and vertical position of the blade. Two GPS receivers supply the guidance system with two points of position, allowing it to calculate what angle the machine is at relative to the site plan.
 - Two GPS receivers allow the system to measure the machine's blade location within 1–2 cm accuracy for precise blade control and machine guidance.
- ▶ A CAES enables the GPS guidance system to be integrated into the machine's hydraulic implement controls.
- ▶ Inertial measurement systems use IMU sensors attached to the body of the machine, blade, or implement. When

attached to the machine body, the positioning or spatial data and the known dimensions of the machine enable the system to precisely calculate the position of a cutting blade at all times.

- ▶ IMU sensors using laser technology are used on excavators since using GPS masts on the boom and stick of an excavator is not practical.
- ▶ LVDT sensors provide closed-loop feedback control for steering and hydraulic system control valves. Essentially, these sensors supply a voltage signal corresponding to a change in length.
- ▶ Electric motor drive systems can be retrofitted to machines, which turn the steering wheel using GPS automated guidance strategies.
- ▶ Terrain compensation is important to autoguidance systems for them to compensate for the effect that varying terrain altitudes can have on the machine's position as measured by the GPS.
- ▶ When installing antennas, receivers, and network modules for retrofit systems, caution must be used to prevent interference caused by the energy from radio signals and to protect the operator from unnecessary exposure to radio energy.

Key Terms

AEMP telematics data standard A communication protocol enabling telematic end users with the freedom to use only one telematics service provider for different brands or makes of machinery.

automatic mode The machine's hydraulics are electronically controlled with no driver intervention to make blade or implement adjustments.

automation The use of control systems that reduce or eliminate human intervention to operate machinery.

binocular cameras Elements of an object detection system required to measure depth or provide stereo vision using the principle of parallax.

CANbus A two-wire network typology that connects modules in parallel.

closed-loop control A process where the operation of an output device is monitored and controlled by a sensor that provides feedback directly to an electronic control unit.

computer-aided earth-moving system (CAES) Integrates GPS data into the machine's hydraulic controls and guidance to autonomously operate a machine's hydraulic implements, such as buckets, shovels, booms, sticks, and blades. As the worksite features change, the machine transmits data about the work it's completed to enable software to update worksite maps, rendering the latest terrain and site conditions.

computer vision A more difficult challenge of recognizing and interpreting the significance of objects using binocular cameras.

controller area networks (CAN) A distributed type of network communication control system. This means no single central control module is used on a machine. Instead, each module or node on the network has processing capabilities

that can not only initiate electrical control for faster response but also synchronize their operation with other network modules.

dead reckoning systems Are a navigation system that depends on only vehicle sensors such as speed, steering angle, and even a magnetic compass to guide a machine. A radio-operated node or signal transmitter may provide a reference point.

differential voltage A signal processing technique used on CANs to transmit serial data with the least amount of signal noise.

fully autonomous A machine control system capable of sensing its environment and navigating without human input.

global positioning system (GPS) also called the global navigation satellite system (GNSS) A worldwide radio-navigation system using satellites to communicate with earth-based radio receivers.

geofencing A feature provided by a telematic service supplier to alert a subscriber to movement of a machine outside a particular geographical area or during expected operating hours.

humans in the loop (HITL) People who provide assistance with autonomous function or other machine support, such as a repair technician.

indicate-only mode A computer-aided earth-moving technique that supplies machine data to a cab terminal, providing feedback about the position of a blade or implement.

inertial guidance systems A type of machine navigation that uses a known starting point, orientation, and velocity to guide a machine. Inertial guidance systems use onboard sensors or instruments that measure speed, direction, and rate of acceleration.

inertial measurement units (IMU) sensors Sensors attached to the body of the machine, blade, or implement. When attached to the machine body, the positioning or spatial data and the known dimensions of the machine enable the system to precisely calculate the position of a cutting blade at all times.

ISO11783 also called ISO-bus A network protocol developed in Germany and used primarily by European agriculture and forestry machines.

J-1939-2 An SAE network protocol used by agricultural and forestry vehicles.

J-1939 An SAE network protocol for off-road HD commercial vehicles

linear voltage differential transformer (LVDT) A linear hydraulic control sensor that supplies a voltage signal corresponding to a change in actuator length. When proportional electrohydraulic valves are used, the movement of the spool valve is proportional to the amount of electrical current passed through the sensor's armature coils.

lidar An acronym for light detection and ranging, which uses pulsed laser beams rather than radio waves to measure distances.

multiplexing A concept where the transmission of more than one electrical signal or message takes place over a single wire or pair of wires.

object or collision avoidance systems Systems that identify objects such as a boulder or a deep hole capable of damaging or even swallowing a machine.

platooning A method of controlling the operation of multiple machines performing the same tasks in a farm field with a single lead machine. Platooning is enabled through machine-to-machine communication or an inter-vehicle communication system and uses only a single operator to control the operation of multiple machines in an agriculture field operation.

precision farmer techniques Farming strategies that use technology such as automated machinery to precisely cultivate, seed, fertilize, and harvest crops.

radar An acronym for radio detection and ranging. It detects objects and determines their distance, angle, and velocity relative to the radio transmitter.

real-time kinematic (RTK) or dual frequency receivers GPS receivers that use a subscription-based signal correction for satellite GPS. RTK can provide positional accuracy to the decimeter or ½ inch on a year-to-year basis.

remote control A machine control system where an operator can use a set of controls that electronically duplicates actual machine controls, enabling the operator to work at a distance.

RFID technology Electromagnetic fields that automatically identify and track objects attached to tags. Information about the object, such as a blade or machine, is electronically stored on the tag and can be read by an RFID reader.

rotating ring laser angle sensors A positional type IMU sensor integrated into the machine's body, boom, stick, and bucket. There are a variety of IMU sensors, but are generally a rotation ring laser combined with mirrors and a specialized laser light sensor or catcher that detects movement.

SAE J-3016 The SAE standard that classifies the level of autonomous control of on-highway vehicles.

smart-iron Off-road equipment integrating some level of telematic, semis autonomous, or fully autonomous machine control.

telematics The transmission and reception of information from remote objects. Typically, GPS signals and onboard network data are transmitted over cell phone or satellite communication systems. The data are analyzed to supply machine information through a web portal.

terrain compensation A feature used by autoguidance systems to compensate for the effect of machine roll, pitch and yaw that varying terrain conditions can have on the machine's altitude position as measured by the roof mounted antenna of a GPS receiver.

triangulation A method using three or more satellite signals to locate position. Triangulation works when a receiver connects with signals transmitted from each satellite at precisely the same time. Since the satellites are located at different distances from the receiver, the signals will arrive at slightly different times.

virtual terminal A screen mounted in the tractor used so that the operator can control connected implements. Modules on ISO-bus machines can transmit what are called virtual objects along the CANbus to be displayed on the virtual terminal.

wireless CAN bridge A connection between the controlled area network of one machine and another. Platooning uses the CAN bridge for machine-to-machine communication, collecting data from the CANbus in one machine and wirelessly transmitting the information to the CANbus in the trailing machine.

Review Questions

1. An automated off-road machine describes off-road equipment that _____.
 - a. is capable of sensing and navigating its environment without human input
 - b. is remote controlled
 - c. has telematic capabilities
 - d. has reduced requirements for human control
2. Which of the following descriptions best describes how the blade or bucket is controlled on a machine that has a computer-aided earth-moving system (CAES)?
 - a. The blade or bucket is automatically guided using telematic signals transmitted from a base station.
 - b. In automatic mode, the operator manipulates hydraulic controls while guided by a cab terminal.
 - c. A 3D site plan will automatically guide the machine to shape site contours.
 - d. A 3D site plan will either guide the operator or automatically control the bucket or blade.
3. Which of the following standards is used to designate a machine's level of autonomous capabilities?
 - a. J-1939-2
 - b. J-3016
 - c. ISO11783
 - d. There is no standard for off-road machinery.
4. Which of the following technologies will be used by a machine using a dead reckoning navigational system?
 - a. A GPS receiver
 - b. Vehicle speed sensor
 - c. A CAN bridge
 - d. Cellular, Bluetooth or a WLAN connection
5. Which of the following technologies is essential in order to enable platooning of machines?
 - a. Radar
 - b. Lidar
 - c. A CAN bridge
 - d. Radio remote control
6. What is the minimum number of satellites signals a GPS receiver needs to identify the location of a machine?
 - a. 30
 - b. 4
 - c. 3
 - d. 1
7. To obtain positional measurement accuracy from a GPS system required for machine navigation and positioning

buckets or blades to an accuracy of less than a ½ inch (1.27 cm) error, which of the following is required?

- a. Signals from four or more satellites
 - b. Two GPS receivers
 - c. A subscription service to correct satellite signal error
 - d. Two different GPS systems such as GLONASS or Galileo
8. To accurately position the centerline of a machine used by computer-aided earth-moving systems, which of the following is a minimum technology requirement?
- a. A single GPS receiver
 - b. Inertial measurement unit (IEU) sensors
 - c. Electric-over-hydraulic controls
 - d. Two GPS receivers
9. Closed-loop feedback control of linear type actuators often use _____.
- a. linear voltage differential transformer (LVDT) sensors
 - b. inertial measurement unit (IMU) sensors
 - c. radio controls
 - d. a pair of CAN bridge modules
10. Terrain compensation feature for GPS-guided machines is necessary to _____.
- a. correct for steering error caused by machine roll, pitch, and yaw
 - b. provide accurate measurement of machine position for collision avoidance systems
 - c. identify GPS satellite errors
 - d. correct for position error when changing altitude

ASE Technician A/Technician B Style Questions

1. Technician A says that the biggest advantage of automating machines is that operator labor is no longer required. Technician B says that automated machines enable the operator to turn their attention to more critical, complex functions. Who is most correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
2. Technician A says that a machine with telematics capability can transmit GPS data wirelessly only if it is linked to a Wi-Fi network. Technician B says a machine with telematics capability will transmit machine and GPS data wirelessly over cellular, satellite, Wi-Fi, and even Bluetooth signals. Who is most correct?
 - a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
3. Technician A and B were discussing the reason for a fully autonomous mine truck to drive to a fuel pump island half way into a work shift. Technician A says that it was likely due to a low fuel level. Technician B says it demonstrates

the need for autonomous machines to have a human in the loop. Who is most correct?

- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
4. Technician A says that closed-loop control of an actuator requires a sensor to monitor the actuator position. Technician B says that closed-loop control of an actuator is performed by the ECM, which supplies signals used to position the actuator. Who is most correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
5. Technician A says that in North America, satellite signals from Russian and American military satellites are used to navigate and locate machine positions. Technician B says that only GPS signals from American satellites are used by machines in North America and around the world. Who is most correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
6. Technician A says that computer-aided earth-moving systems (CAESs) operating with indicate-only capabilities automatically guide buckets and blades of machinery using 3D maps of a construction site. Technician B says that the automatic mode of a CAES provides an operator with site contour images on a cab terminal, which is used to guide the movement of the machine. Who is most correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
7. While discussing the advantages of retrofitting equipment with telematics modules, Technician A said that a subscription for each brand of manufacturer is required for the machines. Technician B said that only one subscription service is required to view telematic data for all the company-owned machines. Who is most correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
8. Technician A says that electronic control modules on a CAN share signal transmission time over the data bus. One module will transmit while all other modules listen. Technician B says the CAN is able to potentially handle both the transmission and reception of data simultaneously from all modules. Who is most correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

9. Technician A says that different network communication protocols are used on equipment made for European and North American markets. Technician B says that there are two different North American network protocols established by the SAE: J-1939 and J-1939-2, with the later used by agricultural and forestry equipment. Who is most correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B
10. Technician A says that the use of two GPS receivers can provide the most precise machine position data for construction, farming, and forestry equipment. Technician B says that excavators cannot use a GPS mast like a bulldozer blade can and therefore cannot use CAES to locate the position of the boom and stick. Who is most correct?
- a. Technician A
 - b. Technician B
 - c. Both Technician A and Technician B
 - d. Neither Technician A nor Technician B

CHAPTER 22

Fundamentals of Hydraulics

Knowledge Objectives

After reading this chapter, you will be able to:

- **K22001** Describe the fundamentals of hydraulics.
- **K22002** Define hydraulic system terminology.
- **K22003** Describe the advantages and disadvantages of hydraulic systems.
- **K22004** Describe Pascal's law.
- **K22005** Describe Bernoulli's principle.
- **K22006** Describe the measurement units used for hydraulic systems.
- **K22007** Describe how pressure and flow are created in a hydraulic system.
- **K22008** Describe positive and negative pressures.
- **K22009** Identify organizations that govern hydraulic system design and safety.
- **K22010** Describe safety concerns unique to hydraulic systems.

Skills Objectives

After reading this chapter, you will be able to:

- **S22001** Calculate pressure, force, and area.
- **S22002** Release pressure from a hydraulic reservoir.

► Introduction

This chapter introduces the fundamental concepts of hydraulic systems and explains terminology specific to hydraulic systems. It describes the advantages and disadvantages of hydraulic systems, explains Pascal's Law, and covers common measurement units used for hydraulic systems. Pressure and flow are defined and explained, as well as positive and negative pressure.

Finally, it covers the organizations that govern industrial standards for hydraulic systems and safety concerns that are specific to hydraulic systems.

► Fundamentals of Hydraulics

K22001

Mobile heavy equipment machines rely on hydraulic systems to power and/or control many of the machines' systems. A machine's **prime mover** (typically a diesel engine, but could be an electric motor or other type of internal combustion engine) is used for power input to drive the system's pump and an actuator (cylinder or motor) is the power output of a **hydraulic system**. Hydraulic fluid is used to transfer energy throughout the system.

► TECHNICIAN TIP

Fluid power is a term that is used to sometimes describe energy transfer systems that use a fluid to transfer energy. Most people only consider hydraulic systems as a fluid power system; however, technically a pneumatic or air system is also a fluid power system.

Many of today's machines feature hydraulic systems that use computers and electronic systems and can share information with other machine systems. Advanced hydraulic systems are covered in later chapters, but the fundamental principles of how hydraulic systems function must be understood before moving into more complicated hydraulic systems. The basic principles of fluid flow and pressure can be applied to several other machine systems as well, and a sound knowledge of hydraulic fundamentals will be invaluable when it comes time to diagnose many different machine system problems. Therefore, it is critical that the information in this chapter is absorbed and understood before moving on.

Hydraulic systems were introduced to mobile off-road equipment several decades ago to eliminate mechanical systems that performed basic tasks like lifting a dozer blade or moving an excavator bucket. These mechanical systems were slow, hard to control, and required a great deal of maintenance. See **FIGURE 22-1** for an older machine with a mechanical implement system. Hydraulic systems are a key part of machines, from small skid steer equipment to massive mining shovels that can fill their buckets with over 30 tons of material, as shown in **FIGURE 22-2**.

FIGURE 22-1 An older machine with a mechanical implement system.

FIGURE 22-2 A massive mining shovel loading a haul truck.

You Are the Mobile Heavy Equipment Technician

You are given a job to diagnose a hydraulic problem on a large wheel loader. The loader has a lot of hours on it but has been serviced regularly since it was new. Approximately three months ago, its tilt cylinder failed and was replaced with an exchange unit.

There have been intermittent hydraulic system issues since then, and the last shift it worked, the operator reported the boom fell onto the side of a truck he was loading. It is also reported to have all functions working slower than normal. It is your job to confirm there is a legitimate problem and correct it.

1. What information would you want to have to start your diagnosis?
2. What are some basic tools you might need?
3. What are three possible causes for these problems?

Hydraulic fluid **flow** and **pressure** are managed by system components to achieve the design parameters set by manufacturers' engineers. These parameters are based on values that a machine needs to achieve such as maximum lifting/digging force, maximum travel speed, or maximum swing torque. The maximum values are limited by prime mover horsepower ratings, hydraulic system design, system adjustments, and structural strength of machine components.

Hydraulic fluid flow is created by the systems' pump(s), and as **pump** flow is directed to an actuator, the result is a physical motion of either a cylinder rod moving or motor shaft turning. A wide variety of machine components can be attached to either cylinder rods or motor shafts. See **FIGURE 22-3** for a backhoe bucket linkage attached to a hydraulic cylinder.

Fluid pressure in the system increases as resistance to actuator motion increases. If system pressure can overcome the load on the actuator, motion will continue; however, if the load increases beyond maximum pressure capabilities of the system, the actuator stops moving or stalls.

To put this in real terms, if an excavator is digging into a pile of loose gravel, there will be very little resistance, and its actuators will keep moving as the operator fills the bucket. However, if the same machine is used to dig wet clay, resistance will be much higher, and at some point, one or more of the machine's actuators will likely stall or stop moving because the hydraulic system pressure can't overcome the resistance.

A properly designed and maintained hydraulic system will provide thousands of hours of operation provided the operator follows recommended operating guidelines, and manufacturer's maintenance guidelines are followed.

Force Multiplication in a Hydraulic System

Hydraulic systems can be compared to mechanical systems that use **mechanical advantage** to multiply force through leverage.

Mechanical linkages can be used to multiply force when the principles of mechanical advantage are applied. A small input force applied can be multiplied several times if the pivot

FIGURE 22-3 A backhoe bucket linkage attached to a hydraulic cylinder.

FIGURE 22-4 How a lever can increase force.

FIGURE 22-5 How force multiplication occurs in a hydraulic system.

point is moved closer to the output. **FIGURE 22-4** shows how a lever can be used to increase force.

The working hydraulic pressure contained in the system is applied to all internal surfaces it contacts. Input forces can be multiplied by simply increasing the surface area of the actuator (output component) that is exposed to the working hydraulic pressure.

This is similar to how **force multiplication** occurs in a mechanical system. See **FIGURE 22-5** to visualize force multiplication in a hydraulic system.

When system pressure is applied to larger surface areas, greater output force is created.

The trade-off that results when force multiplication occurs is that actuator speed and travel is reduced. This is also like a mechanical lever whereby as the pivot point is moved closer to the output the output travel distance is reduced in comparison to the input travel applied and the input vs. output speed differential increase.

► Hydraulic System Terminology

K22002

Hydraulics is a general term applied to the study of **fluids** (**liquid** or **gas**), typically in an enclosed system. Hydraulic **fluid power** is a specific area of hydraulics in which a liquid is used to transmit energy and power to one or more **actuators** to provide a force to move a load. Such systems are often referred to as *hydraulic systems*.

Flow in a hydraulic system refers to the movement of fluid within the system and is measured in units of volume per one

unit of time. Most commonly **gallons per minute (gpm)** or **liters per minute (lpm)** are used to measure flow.

Pressure in a hydraulic system is created by the resistance against fluid flow. It is measured in units of force applied to one unit of area. Pounds per square inch (psi) or kilograms per square centimeter (kg/cm^2) are common units of hydraulic system pressure measurement. However, there are other units of pressure measurement, such as inHg (inches of mercury), inH₂O (inches of water), atm (atmospheres), bars, and kPa (kilopascals).

Hydrodynamics refers to the study of hydraulic systems where a high volume of fluid is in motion at a high velocity in an enclosed but loosely sealed system, and how the fluid acts on components in that system. A powertrain torque converter is a good example of a component that relies on fluid in motion to transfer energy. These systems rely more on fluid inertia than fluid pressure.

Hydrostatics refers to the study of fluid in an enclosed and tightly sealed system where the fluid is at rest and either under pressure or not. Machines that use fluid power to drive tracks or tires are quite often referred to as having hydrostatic drives. Although this is not in line with the true definition of “hydrostatic,” the term is used frequently.

Pumps are needed in any hydraulic system to produce fluid flow, and without flow, no work can be accomplished.

Actuators are the output components that receive fluid flow and convert it into motion. Cylinders produce linear motion for tasks like lifting dozer blades up and down, whereas motors produce rotary motion, for example, to make tracks rotate.

Pneumatics is a specific area of hydraulics in which a gas (usually air) is used to transmit energy and power to one or more actuators to provide a force to move a load. Pneumatic systems are mostly limited to use in brake systems on some MORE machines; however, some rock drills are completely pneumatically powered.

► Advantages and Disadvantages of Hydraulic Systems

K22003

The fundamental operating concept of all hydraulic systems is the use of fluid to transfer energy. One of the main advantages of hydraulic systems is that they can be designed to move very heavy loads by applying hydraulic pressure to the movable part of an actuator.

Mechanical linkages are unnecessary within a hydraulic system, as fluid can be routed anywhere on a machine through tubes and hoses. Fluid power is then used to transfer the required force from the component exerting the initial force (pump) to the component exerting the moving force (actuator).

Hydraulically powered equipment also has the advantage of having fewer exposed mechanical parts that can wear and break down. Hydraulic systems are self-lubricating and compact, with high power density, and rely on multiplication of forces, whereby a small force can control large forces.

There are also disadvantages to hydraulic systems, such as the potential for equipment failure when hoses fail and the

hydraulic fluid leaks. However, the disadvantages are far outweighed by the advantages of these systems.

Advantages of Hydraulic Systems

The following list summarizes the main advantages of hydraulic systems:

- **Reduced maintenance:** Hydraulic systems do not require complicated systems of gears, cams, cables, or linkages, and the wear and distortions associated with these components is dramatically reduced.
- **Precise control:** Position, speed, and other control parameters can be controlled very precisely and can be performed the same way repeatedly.
- **Immediate reaction:** Because hydraulic fluid is practically incompressible, when an operator moves a joystick to actuate a hydraulic function, the system reacts almost immediately. This is unlike a pneumatic system, which reacts with a delay because gases are compressible.
- **Multiplication of force:** Hydraulic system force multiplication allows for relatively small actuators at the point of force application, compared to other types of systems.
- **Flexibility:** Components can be conveniently located at widely separated points.
- **Construction:** Although numerous components may be required, some of which can be complicated, the actual construction of a system is simple.
- **Seamless speed control:** Speed variations can be accomplished without shifting gears or interrupting the power flow.
- **Ability to turn corners:** Fluid conductors can be designed to transmit fluids up, down, and around corners, without significant losses in efficiency. See **FIGURE 22-6**.

Disadvantages of Hydraulic Systems

The following list summarizes the main disadvantages of hydraulic systems:

- **High pressures:** Hydraulic systems require strong components that are precisely machined to withstand the high fluid pressures applied to them.

FIGURE 22-6 How hoses can direct fluid flow around a corner.

- **Relatively low efficiency:** Naturally occurring internal leakage in components (particularly pumps and hydraulic motors), as well as pressure losses in valves and piping, leads to lower overall system efficiencies compared to most other types of power transmitting systems.
- **Cleanliness requirements:** To ensure long component life and optimum efficiency, hydraulic fluids must be kept extremely clean and free of contaminants.
- **Safety:** High-pressure fluids can be a serious safety hazard in the case of hose ruptures or broken tubes and fittings.
- **Fire hazard:** All hydraulic fluids are flammable to a certain extent. Fluids must not be exposed to open flames or high-temperature heat sources.
- **Environmental hazard:** Hydraulic leaks can be damaging to the environment, and proper disposal of hydraulic fluids can be costly.
- **Leaks:** Fluid leaks and spills can be hazardous. **FIGURE 22-7** shows a hydraulic leak.

► Pascal's Law and Hydraulic Systems

K22004

The operating principles of today's hydraulic systems are embedded in the scientific principles of **Pascal's law**, which dates from the 1600s. To this day, even the most sophisticated modern equipment still operates on these principles. Pascal's law is described in the following section.

Pascal's Law

In the 1600s, Blaise Pascal observed the effects of pressure applied to a fluid in a closed system. Pascal's law states that pressure applied to a confined liquid is transmitted undiminished in all directions and acts with equal force on all equal areas, and at right angles to those areas.

This means that pressure exerted on a confined fluid at rest is transmitted equally in all directions, is the same at any point in the liquid, and is exerted at right angles to the walls of the container.

FIGURE 22-7 Hydraulic fluid leak.

If you were to fill a glass wine bottle to the top with water and force a cork into the bottle, you would be increasing pressure throughout the entire inside of the bottle. The pressure would be transferred by the water to the entire inside of the bottle and would act at right angles to the inside bottle surface.

If you could put a gauge in different locations around the bottle, you would see the pressure is the same anywhere you measured it. Because liquids are practically incompressible, the pressure would rise quickly if you kept pushing the cork, and eventually a weak spot in the bottle would fail. **FIGURE 22-8** demonstrates how pressure is created in a sealed container.

Taking hydraulic braking systems as an example, Pascal's law is the operating principle behind this everyday application. Pressure that develops in the master cylinder is transmitted through the hydraulic braking system as long as the system remains closed and has no leaks. At the actuators (brake calipers or wheel cylinders), there is a resistance to fluid flow as the fluid moves the brake component and pressure builds. **FIGURE 22-9** shows how fluid pressure is transferred through a hydraulic brake system.

In a closed system, hydraulic pressure is transmitted equally in all directions throughout the system. What happens to the pressure levels if there is a leak in the system? According to Pascal's law, a substantial leak will prevent the pressure from building up because there is very little resistance to flow. The result is that the pressure within the whole system will be equally low. This means that the vehicle may lose some or all of its braking ability if a leak develops, as pressure cannot be developed. **FIGURE 22-10** shows what happens to pressure in a hydraulic brake system when a leak develops.

FIGURE 22-8 How pressure is created in a sealed container.

© 2006 Eaton, All Rights Reserved. Reproduced with permission from Eaton.

FIGURE 22-9 How fluid pressure is transferred through a hydraulic brake system.

FIGURE 22-10 How pressure drops in a brake system when a leak develops.

Pascal's law also helps in diagnosing problems with hydraulic systems. For example, in the case of a brake system, if the brake pedal is squishy (soft or spongy), there is a good chance that the hydraulic braking system has air in it. This is because air is compressible and has to be removed by bleeding it out. If the brake pedal slowly sinks to the floor, there is likely a small leak in the system that must be found. If the vehicle pulls to one side, it could be that a brake hose is plugged or a line pinched, and is not allowing fluid to transfer pressure to one of the brake units.

To demonstrate Pascal's law, follow the guidelines in **SKILL DRILL 22-1**.

► Bernoulli's Principle

K22005

The principle is named after Daniel Bernoulli, who published it in his book *Hydrodynamica* in 1738. Bernoulli's principle states that a rise in pressure in a flowing fluid must always be accompanied by a proportionate decrease in the speed, and conversely an increase in the speed of the fluid results in a decrease in the pressure. As oil flows through a system and is made to speed up,

there will be a pressure drop, and inversely, if the speed of oil flow decreases, its pressure will increase.

A practical application of this principle for technicians would be when they are replacing a hose or tube on a machine. Care must be taken to ensure the replacement hose or tube is the same inside diameter as the one being removed. Otherwise, a pressure drop or increase will occur and may affect system performance. Dramatic changes in fluid velocity across a valve may create force imbalances on the valves spool and result in erratic operation.

► Measurement Units for Hydraulic Systems

K22006

Both metric (International System of Units, or SI) and/or Standard (Imperial) measurement units can be found in manufacturers' service information when hydraulic system values are being discussed. The units used usually relate to where the machine was designed and/or manufactured and the common measurement system used by the manufacturer. Some examples are listed in **TABLE 22-1**.

► TECHNICIAN TIP

To get an understanding for the different measurement units that manufacturers may use, do an Internet search for the machine specifications for a new excavator. You should be able to download a brochure that shows the specifications for the machine's hydraulic system. Compare a few different manufacturers' excavators to see what units are used. This will also give you an idea as to what normal pressure and flow settings are for new machines. Try comparing other types of machines' hydraulic system specifications.

Several online tools and smartphone apps are also available to use for unit conversion if the measuring device you are using does not correspond to the service information you have.

SKILL DRILL 22-1 Demonstrating Pascal's Law

For this procedure, you need the following tools, materials, and equipment:

- Small hydraulic cylinder with a trunnion, clevis, or pivot mount to allow the cylinder to be suspended, and a pivot eye on the end of the rod
- Frame from which to suspend the cylinder
- Hand pump with pressure gauge
- Pressure gauge
- T-fitting for attaching the hand pump and the pressure gauge to the rod-end port of the cylinder
- Weights and chain or cable to suspend the weights from the cylinder
- Spanners and wrenches of appropriate sizes
- Pencil
- Paper
- Safety glasses or goggles
- Gloves

1. Put on safety glasses or goggles, and gloves.
2. Assemble the test setup.
 - a. Suspend the cylinder from the frame.
 - b. Insert the tee fitting into the rod-end port of the cylinder.
 - c. Attach the pressure gauge and the hand pump to the T-fitting.
4. Demonstrate Pascal's law.
 - a. Attach a light weight to the cable or chain attached to the cylinder rod.
 - b. Use the hand pump to suspend the weight above the floor.
 - c. Record the pressure on both pressure gauges (hand pump and cylinder).
 - d. Lower the weight to the floor.
 - e. Attach additional weights to the cable or chain.
 - f. Use the hand pump to suspend the weights above the floor.
 - g. Record the pressure on both pressure gauges.
 - h. Repeat several times, using increasing weight.
 - i. Report your conclusions.
 - j. Clean work area, and return tools and equipment to proper storage.

TABLE 22-1 Common Measurement Units for Hydraulic Systems and Abbreviations

Pressure	
Unit	Abbreviation
Pounds per square inch	Psi
Kilograms per square centimeter	Kg/cm ²
Pascal	Pa, kPa, hPa
Inches of water	inH ₂ O
Bar	bar
Inches of mercury	inHg
Atmosphere	Atm
Flow	
Unit	Abbreviation
Liters per minute	lpm
Gallons per minute	gpm
Speed	
Unit	Abbreviation
Feet per second	fps
Meters per second	mps

► **Hydraulic Pressure and Flow**

K22007

One critical point to remember when trying to understand the operating principles of a hydraulic system is this: pumps create fluid flow, not pressure. The pressure in a hydraulic system is determined, for the most part, by the load the system must move. There is also inherent resistance to flow created by all the components that are part of the system. All hoses, valves, tubes, filters, coolers, and actuators naturally have a resistance to flow in them. This value is usually insignificant and should be acceptable if the system is designed properly, but it can be excessive under certain circumstances such as extreme cold weather. The hydraulic fluid’s **viscosity** (resistance to flow) is also a factor to consider when looking at residual pressure (no load pressure) in the system.

The load on an actuator creates a resistance to pump flow, and that in turn develops the working pressure in the system. As loads change during a typical work cycle, the system pressure changes. As loads increase, resistance to flow increases, and an increase in system pressure follows. When the load on an actuator decreases, then a reduction in system pressure follows. Maximum system pressure is limited by a main relief valve, to keep pressure values to a safe limit. See **FIGURE 22-11** for a large load on a hydraulic actuator. Pressure is measured in units of force per one unit of area (**pounds per square inch or kilograms per square centimeter**).

Force is the outcome of fluid pressure being applied to an actuator (cylinder or motor). A cylinder outputs a linear force when fluid pressure is applied to its piston, and a motor outputs

FIGURE 22-11 An actuator with a large load on it.

a rotary force (torque) when it receives pump flow. Linear force is measured in pounds, kilograms, or newtons, and rotary force is measured in foot-pounds (ft-lb) or newton meters (N·m)—the amount of rotational force 1 foot or 1 meter from the center of the rotary actuator shaft.

Varying amounts of mechanical force can be extracted from a single amount of hydraulic pressure. Because pressure is force per unit area (e.g., 3.45 bar, or 50 pounds per square inch [psi]), the same pressure applied over different-sized surface areas will produce different levels of force. See **FIGURE 22-12** to visualize how system pressure can act on several actuators and produce different force outcomes.

Engineers apply hydraulic principles to create varying amounts of mechanical force in hydraulic braking systems. As a practical example, this principle allows engineers to design automotive brakes to have a precise amount of braking force at each wheel. For instance, the front wheels on some front-wheel drive vehicles can produce up to 80% of the vehicle’s stopping power because of the weight distribution and weight transfer. For these vehicles to brake smoothly, more pressure must be applied to the front brake units than the rear brake units. This is accomplished through the front and rear brake pistons. The larger brake pistons on the front wheels give greater mechanical force and braking power to the front wheels.

FIGURE 22-12 How one pressure can act on several actuators, with different force outcomes.

► TECHNICIAN TIP

Keep in mind when thinking about automotive brake systems that there is very little fluid flow required to make the brakes work. There will be a small clearance between the wheel brake friction material (brake pads or shoes) and the rotating member (rotor or drum) and only a small amount of fluid is needed to move the friction material against the rotating member. This is one type of hydraulic system that relies more on pressure than flow to achieve its designed performance outcome.

Figure 22-12 illustrates a hydraulic system that has cylinders of different sizes. When the brake pedal is pressed, the force against the piston in the master cylinder applies pressure to the brake fluid. Because the wheel brake actuators are being forced against a stationary object, as input force increases, then fluid pressure increases in direct proportion.

This same pressure is transmitted equally throughout the fluid, but each output piston develops a specific amount of **output force**, depending on its diameter (surface area). The top cylinder is smaller than the master cylinder, so the amount of force it exerts will be less than the force applied to the master cylinder. The middle cylinder is the same size as the master cylinder, so its output force will be the same. The bottom cylinder is larger than the master cylinder, and so its force will be greater.

► TECHNICIAN TIP

Input force, output force, and working pressure are optimized during the design of the hydraulic system, based on a specific equipment application. This is one reason why it is never acceptable to arbitrarily substitute hydraulic components from another piece of equipment.

Flow Rate and Speed of Actuator

The speed at which a load can be moved depends on the delivered flow rate and the size of the actuator that is receiving the flow. Hydraulic oil must circulate within a system for it to transmit energy to the working components. Without oil flow, most systems cannot work. Hydraulic flow is normally produced by using a positive displacement pump. This type of pump is discussed in detail in an upcoming chapter; however, a positive displacement pump produces fluid flow any time it is being driven.

Hydraulic fluid flow occurs when there is a pressure differential. In other words, fluid always flows toward a lower pressure in a manner similar to how a river flows to a lower elevation. At a pump's inlet, a low pressure is created when the pump starts turning, and this forces fluid that is in the reservoir to move into the pump. Once it leaves the pump outlet, the fluid then continues flowing through the system toward the reservoir that is at a lower pressure. At the pump outlet, fluid is at a higher pressure because of the system pressure created by the load, and the fluid flows toward a lower pressure at the reservoir. **FIGURE 22-13** depicts how oil flows from high pressure to low pressure.

FIGURE 22-13 How oil flows from high to low pressure.

Three main points are critical to understanding hydraulic flow:

1. For a hydraulic system to create work, the hydraulic fluid must apply pressure to an actuator. An actuator is a device that converts fluid power to mechanical power, like a hydraulic cylinder or rotary motor. For instance, on a dozer the lift cylinder controls the up/down movement of the blade. Fluid pressure applied to the cylinder piston moves the rod into the cylinder, which in turn lifts the blade. The amount of pressure needed to lift the blade is determined by the weight of the blade and the size of the cylinder piston.
2. The rate of flow to an actuator is measured in liters per minute (lpm) or gallons per minute (gpm), and the flow rate determines the speed of the actuator. The flow is delivered by the pump.
3. The actuator speed changes when the rate of flow to the actuator changes. Speed of a linear actuator is measured in feet per second (fps) or meters per second (mps) while rotary actuator speed is measured in revolutions per minute (rpm).

When the flow rate to a linear actuator is increased, rod travel speeds up, and if the flow rate to a rotary actuator is increased, its output shaft speeds up. For example, to lift a dozer blade faster, there has to be a higher rate of fluid flow delivered to the cylinders from the pump.

► Positive and Negative Pressure

K22008

All hydraulic system pressure is measured in comparison to either atmospheric pressure or a perfect vacuum. Atmospheric pressure at sea level is 14.7 psi (1.01 bar, or 101.35 kPa), which is the weight of the column of atmospheric air that is applying force to a 1-inch square area at sea level. If exposed to the atmosphere, most gauges read 0 at sea level and approximately room temperature. The face of the gauge may say “psig,” which stands for psi gauge.

If a gauge is calibrated to be an absolute gauge, it would read 14.7 psi at sea level. Although these gauges aren’t as popular as psig gauges, you might see “psia” on the face of an absolute gauge to indicate how it is calibrated.

If you measured system pressure anywhere between the pump outlet and the work port of an actuator, you would read

FIGURE 22-14 A gauge that can read both positive and negative.

a positive pressure. That is, it would be above 0 psig. Negative pressure occurs when fluid pressure falls below 0 psig. There should only be two places in a system where a negative pressure occurs—at the pump inlet and under some circumstances in an actuator when the load overcomes the oil supplied to it. Negative pressure is sometimes referred to as vacuum (in reality it's a partial vacuum), and a pump inlet line is sometimes called a suction line.

See **FIGURE 22-14** to look at a gauge that can read positive and negative pressure.

► Organizational Bodies Governing Industrial Standards

K22009

Several international bodies maintain standards for hydraulic systems and components. These organizations ensure that safety is maintained for those working in the industry by ensuring that the design and manufacture of the equipment and components used in different systems meet the minimum specifications for the applications in which they are deployed.

ASTM International

ASTM International, formerly the American Society for Testing and Materials, develops voluntary consensus standards of quality, safety, and market access across a broad range of industries.

American National Standards Institute

The American National Standards Institute (ANSI) oversees the creation and dissemination of norms and guidelines for business and is involved in accreditation of standards-based programs. ANSI is the U.S. representative to the ISO.

International Organization for Standardization

The International Organization for Standardization (ISO) is the world's largest developer and publisher of international

standards. ISO is a nongovernmental organization comprised of representatives from the national standards institutes of numerous countries throughout the world.

Joint Industrial Council

Though the Joint Industrial Council (JIC) is now defunct, the organization's hydraulic standards are still widely recognized and frequently referenced, and persist in legacy parts codes and schematics. There is one commonly used series of metal to metal angled face connectors that are referred to as JIC.

Society of Automotive Engineers

The Society of Automotive Engineers (SAE) is an international association of engineers and related technical experts. SAE develops voluntary consensus standards for the aerospace, automotive and commercial vehicle industries.

► Calculating Force, Pressure, and Area

S22001

This section describes the relationship between force, pressure, and area. It reviews Pascal's law and provides the formulas, with examples, that you will need to be able to calculate force in both a single-acting cylinder and a double-acting hydraulic cylinder. To make calculations regarding pressure or force of a hydraulic cylinder, you first need to determine the area of the piston.

Area of Circles

Linear actuators (cylinders) transfer fluid power in a hydraulic system using pistons, which consist of a circular surface (piston head) moving within a sealed cylinder. The piston is connected to a rod that moves in and out of the cylinder. The piston surface area is an essential part of force, pressure, and speed calculations. To understand how to make calculations for actuator force, pressure, and speed, one must first understand the properties of circles. There are three main measurements of a circle: the radius, the diameter, and the circumference.

Radius

The radius is a line from the center of the circle to its boundary and is denoted with a lowercase r . In hydraulics applications, the radius often must be derived from the diameter of the piston or the bore of the cylinder. See **FIGURE 22-15** for the different measurements of a circle.

Diameter

A diameter is a line that crosses a circle passing through the center and is denoted with a lowercase d . The diameter of the piston or bore of the cylinder is usually a known quantity.

Circumference

The circumference is the distance around the outside of a circle and is denoted with a capital C .

FIGURE 22-15 The three different measurements of a circle.

Circumference is not normally considered when it comes to calculating hydraulic system equations. The circumference of the piston can be calculated using the following formula: $C = \pi d$.

Relationship Between the Parts of a Circle

There are mathematical relationships between different parts of a circle. These relationships can be used to calculate an unknown value if two other values are known.

Diameter and Radius

The diameter of a piston is twice the length of the radius, which is expressed as $d = 2r$.

The radius of a piston is half the length of the diameter, which is expressed as $r = \frac{d}{2}$.

The circumference of a circle divided by its diameter equals pi (π):

- Pi is a Greek letter that is represented by the symbol π .
- $\pi = 3.1415927 \dots$ (Note: The ellipses (...) means that the number goes on into infinity.)
- If you take the circumference of any circle and divide it by its diameter, you will always get this number, no matter what size the circle is.

Calculating the Area of a Circle

The formula for calculating the area (A) of a circle is $A = \frac{\pi d^2}{4}$ or πr^2 .

All answers must be in square units, such as in.², cm², and mm².

Example 1

Calculate the surface area of a piston, using radius (r), as depicted below:

$$\begin{aligned} r &= 3 \text{ cm} \\ r^2 &= 9 \text{ cm} \\ A &= \pi r^2 \\ A &= 3.14 \times 9 \text{ cm} \\ A &= 28.27 \text{ cm}^2 \end{aligned}$$

FIGURE 22-16 A circle with a radius of 3 cm and an area of 28.27 cm².

FIGURE 22-16 shows a circle divided into squares that represent one square centimeter each.

Example 2

Calculate the surface area of a piston, using diameter (d), as depicted below.

$$\begin{aligned} d &= 15 \text{ cm} \\ A &= \frac{\pi \times (15)^2}{4} \\ A &= \frac{\pi \times (15 \times 15)}{4} \\ A &= \frac{\pi \times 225}{4} \\ A &= \frac{3.14159 \times 225}{4} \\ A &= \frac{706.85775}{4} \\ A &= 176.71 \text{ cm}^2 \end{aligned}$$

Formula for Pascal's Law

Pascal's law states that pressure applied anywhere to a body of fluid causes a force to be transmitted equally in all directions.

To solve for force, Pascal's law may be mathematically expressed as:

$$F = p \times A$$

where:

F = Force

p = Pressure

A = Area

(Force = Pressure multiplied by Area)

This may be inverted to solve for pressure:

$$p = F \div A$$

(Pressure = Force divided by Area)

Force is measured in kilograms (kg); area is measured in square centimeters (cm²); and pressure is measured in kg/cm², or bar if working in SI (metric) units. In the imperial system, force is measured in pounds (lb), pressure in pounds per square inch (psi), and area in square inches (in.²).

Calculating Force Output in a Single-Acting Cylinder

Single-acting cylinders only have one port in their barrel to allow fluid to apply pressure to the bottom of its piston.

1. First calculate the area of the piston, using the following formula:

- Area (A) equals π (or pi) multiplied by the square of the piston's radius (r):
- $A = \pi r^2$

Note: In hydraulics applications, the diameter of the piston (same as cylinder bore) is often known. Use the bore, or interior diameter of the cylinder, to calculate the radius.

- Radius is half the diameter (d) of the cylinder, or:

$$r = \frac{d}{2}$$

- Though usually calculated in terms of radius, area can also be calculated in terms of diameter, as follows:

$$A = \frac{\pi \times d^2}{4}$$

► TECHNICIAN TIP

The decimal representation of π is infinite and therefore must always be approximated. Always approximate π consistently throughout an equation or series of equations. Note that rounding π to two places of decimals (3.14) is adequate for illustration purposes; for real-world applications, greater precision (3.14159 ...) may be required.

2. To use a cylinder's area to solve for force (or pressure), using Pascal's law, follow the steps in the following examples.

Example 1

Determine the force produced by a cylinder with a 5 cm diameter if the operating pressure is 140 bar (143 kg/cm²). Use your calculator when plugging in π , rather than the rounded number; that is, 3.14159 ...

- Use the formula $F = p \times A$.
- Pressure (p) is a known quantity: 140 bar.
- Calculate area (A), using the diameter of the cylinder (d):

$$A = \frac{\pi d^2}{4}$$

$$A = \frac{\pi (5)^2}{4}$$

$$A = \frac{\pi 25}{4} = \frac{78.5}{4}$$

$$A = 19.625 \text{ cm}^2$$

- Plug pressure (p) and area (A) into the formula, and solve:

$$F = p \times A$$

$$F = 140 \text{ bar} \times 19.625 \text{ cm}^2$$

$$F = 2747.5 \text{ kg}$$

Single-acting cylinder with a 5 cm diameter piston and having a pressure of 140 bar applied to it.

Example 2

Determine the pressure required for a cylinder with a 7.62 cm bore to move a 5,500 kg load.

- Use the formula $F = p \times A$.
- Load (F) is a known quantity: 5,500 kg.
- To find the formula for calculating pressure, divide both sides by A :

$$F = pA$$

$$\frac{F}{A} = \frac{pA}{A}$$

$$\frac{F}{A} = p$$

$$p = \frac{F}{A} \text{ or } p = F \div A$$

- Calculate area (A), using the bore/diameter of the cylinder.
- Plug in the values to calculate the pressure.

Single-acting cylinder with a 7.62 cm bore moving a load of 5,500 kg.

Calculating Force in a Double-Acting Cylinder

In a double-acting cylinder, force capability is different on extension versus retraction. On retraction, the area subjected to hydraulic pressure is less than on extension because the area taken up by the rod is not used to move the load. On extension, the effective area is the entire face of the piston; on retraction, the **effective area** is the piston area minus the rod area.

► TECHNICIAN TIP

To prevent confusion, use subscript to distinguish multiple related terms (A_{rod} versus A_{piston}) in an equation.

1. To calculate the effective area on extension (entire face of piston), use the formula:

$$A_{\text{piston}} = \frac{\pi d_{\text{piston}}^2}{4}$$

2. To calculate the extension force, use the formula:

$$F_{\text{extension}} = p \times A_{\text{piston}}$$

3. To calculate the effective area on retraction (piston area minus rod area), use the formula:

$$A_{\text{effective}} = A_{\text{piston}} - A_{\text{rod}}$$

4. The rod area is calculated like the piston area:

$$A_{\text{rod}} = \frac{\pi d_{\text{rod}}^2}{4}$$

5. To calculate the retraction force, use the formula:

$$F_{\text{retraction}} = p \times A_{\text{effective}}$$

Example 1

Determine the extension and retraction force capabilities of a double-acting cylinder if the cylinder bore is 7.62 cm and the rod diameter is 2.54 cm. The pressure available is 100 bar.

1. Calculate extension force.

- Calculate extension force, using the formula:

$$F_{\text{extension}} = p \times A_{\text{piston}}$$

- Pressure is a known quantity: 100 bar.

- Calculate area (A), using bore/diameter of cylinder (d):

$$A_{\text{piston}} = \frac{\pi d_{\text{piston}}^2}{4} = 45.6 \text{ cm}^2$$

- Plug in the values to calculate the extension force:

$$\begin{aligned} F_{\text{extension}} &= p \times A_{\text{piston}} \\ &= 100 \times 45.6 \\ &= 4,560 \text{ kg} \end{aligned}$$

2. Calculate retraction force.

- Calculate retraction force, using the formula:

$$F_{\text{retraction}} = p \times A_{\text{effective}}$$

- Calculate effective area, using the formula:

$$A_{\text{effective}} = A_{\text{piston}} - A_{\text{rod}}$$

- First, calculate piston area and rod area:

$$A_{\text{piston}} \text{ (solved above)} = 45.6 \text{ cm}^2$$

$$A_{\text{rod}} = \frac{\pi d_{\text{rod}}^2}{4} = \frac{\pi (2.54)^2}{4}$$

$$A_{\text{rod}} = 5.07 \text{ cm}^2$$

- Then plug in the numbers to determine effective area:

$$A_{\text{effective}} = A_{\text{piston}} - A_{\text{rod}}$$

$$A_{\text{effective}} = 45.6 \text{ cm}^2 - 5.1 \text{ cm}^2$$

$$A_{\text{effective}} = 40.5 \text{ cm}^2$$

- Plug in the values to calculate retraction force.

$$F_{\text{retraction}} = p \times A_{\text{effective}}$$

$$F_{\text{retraction}} = 100 \text{ bar} \times 40.5 \text{ cm}^2$$

$$F_{\text{retraction}} = 4,050 \text{ kg}$$

Double-acting cylinder with a piston diameter of 7.62 cm and a rod diameter of 2.54 cm, with 100 bar pressure applied to it.

You can conclude from these calculations that the cylinder has roughly 500 kg less retraction force than extension force because of the smaller surface area that the fluid pressure can be applied to.

Example 2

Determine the pressure required for the double-acting cylinder in Example 1 to extend and retract a 6,800 kg load.

- Area of the piston is a known quantity (from Example 1):

$$A_{\text{piston}} = 45.6 \text{ cm}^2$$

- Remember that $p = F \div A$

$$p_{\text{extension}} = F \div A_{\text{piston}}$$

$$p_{\text{extension}} = \frac{6,800}{45.6}$$

$$p_{\text{extension}} = 149 \text{ bar}$$

- Calculate the retraction pressure, using the effective area ($A_{\text{effective}}$) from Example 1 (40.52 cm²):

$$p_{\text{retraction}} = F \div A_{\text{effective}}$$

$$p_{\text{retraction}} = \frac{6,800}{40.5}$$

$$p_{\text{retraction}} = 168 \text{ bar}$$

Double-acting cylinder with a 6,800 kg load on it and the pressure needed to move it.

You should conclude from these calculations that as the load on the cylinder increases, there must be a proportionate increase in pressure applied to the piston to move the load.

Practice using the $F = P \times A$ formula with your own piston dimensions, loads, and pressure values. This will help you understand the relationship between force, pressure, and area.

► Safety Concerns Related to Hydraulic Systems

K22010

Minor injuries, such as burns, and serious injuries or even death have resulted from technicians not being aware of potential dangers inherent to hydraulic systems. Hydraulic systems use hot, high-pressure fluids to transfer large amounts of energy, and personal harm can occur quickly if a technician isn't proactive in preventing an accident.

Incidents can happen because of improper testing methods or use of improper test equipment, such as using underrated hoses or gauges. Use of inadequate replacement parts such as hoses, seals, or tubes can result in the rupture of these components, and not only the escape of hot, high-pressure fluid but also the sudden uncontrolled movement of machine components could have disastrous results. A little common sense and proper use of PPE will go a long way to keeping you and your coworkers safe when working on hydraulic systems. You should always refer to the specific manufacturer's service information for the machine before performing any servicing or repairs to hydraulic systems.

These safety concerns also apply to hydraulic tools such as presses, which can operate at extreme pressures. You will see lots of warnings and cautions on machines and in service information so don't overlook them and become another statistic. Here are a few types of specific safety concerns that you should be aware of and some tips that help you avoid injuring yourself or others.

Oil Injection

Heavy equipment hydraulic systems operate at high pressures that are typically around 3,000–5,000 psi and can sometimes exceed 10,000 psi. This high pressure can be used to perform many high-force machine operations, but if that pressure is allowed to escape, and your skin or other body parts are exposed to it, some very serious consequences can occur. Skin can be punctured easily by high-pressure fluid, and if hydraulic fluid gets into your bloodstream, there is a good possibility of getting blood poisoning, which in turn could lead to death.

If you are looking for the source of a hydraulic leak on a machine and see oil dripping, this should raise a red flag for you. Although the oil looks like it is dripping harmlessly, it may in fact be spraying out under high pressure and waiting to do harm if you put your hand in its path. Be very cautious, and use a piece of cardboard, rubber, or wood to identify where the leak is originating. See **FIGURE 22-17** for a warning label for oil injection injury.

An oil injection accident is very serious and can easily result in an amputated limb or worse. To see the result of an oil injection injury, see **FIGURE 22-18**.

Trapped Pressure

Pressure can be trapped inside many hydraulic components even after the machine is shut off. If you need to replace a hose,

FIGURE 22-17 A warning label for oil injection injury.

Image Provided As Courtesy of John Deere.

FIGURE 22-18 An oil injection injury.

tube, or other component at any time, the pressure inside that component must be reduced to safe levels. This may not be easy to do, and you should always refer to the appropriate service manual for proper procedures. Releasing pressure or bleeding off pressure can be very dangerous if done improperly. Always keep in mind, if you are releasing trapped hydraulic pressure, there's a good chance that some part of the hydraulic system is going to move.

SAFETY TIP

Always refer to the machine manufacturer's service information to learn how to release pressure safely. In some cases, you may need special tooling to safely release trapped pressure. Follow these procedures carefully and completely to ensure the safety of you and your coworkers.

Once you confirm all system pressure is released, perform appropriate lockout and tagout procedures for the particular machine you are working on. This procedure should follow all company and government requirements.

Crushing Hazards

A crushing hazard is present on a machine where there is the potential of machine components that can move and squeeze or crush you or your body parts. A good example of the pivot point or articulation joint of an articulated steering wheel loader. If a machine has hydraulic functions that can create crushing hazards, you must be very wary that you do not put yourself in a vulnerable position when working on the hydraulic system. Make sure any component that could move and cause a crushing injury will be mechanically held in place. Steering locks and boom cylinder supports are two examples of mechanical locks that must be installed if you're going to be working near crushing hazards.

Burns

Hydraulic systems can generate high amounts of heat, and this should be another safety concern for the technician. Burns to your body can occur at just over 100°F (38°C). You need to make sure that you take precautions to avoid getting burnt if you are servicing or repairing a hydraulic system that has just recently been operating. You should consider using a heat gun to ensure safe component temperature before proceeding. At times it will be unavoidable to work on a machine with hot hydraulic fluid, and if this is the case, you should use the proper PPE to keep yourself protected.

SAFETY TIP

Testing or adjusting a running piece of equipment should be avoided, but sometimes it is necessary to do so. If you need to work on a running machine, your senses should be on high alert. If someone else is running the machine you are working on, you must keep clear communications with that person to let him or her know what you want done. This is sometimes difficult, as a running machine can be very noisy, but the person operating the machine must be absolutely sure about what is required. If you are unsure of the operator's capabilities, stop and find someone whom you feel confident with. Even the smallest mistake when working on a running machine could be deadly.

Slips and Falls

Hydraulic fluid is slippery by nature, and if that fluid is leaked onto a surface that is walked on or a grab handle that is needed, a slip hazard is created. This could be a problem not only with a machine operator slipping and falling, but also for the technician at risk from fluid that has spilled or sprayed as a result of servicing or repairing the hydraulic system. Hydraulic leaks in a machine's cab can create slip hazards. Make sure that all spilled fluid is cleaned up, and leaks that create slip hazards are repaired.

Fire Hazards

Hydraulic fluid is usually mineral-based oil, which is flammable. More than one machine has caught fire and burnt up because of a hydraulic leak that has either been sprayed onto a turbocharger or ignited by welding sparks or a torch. You need to be careful when welding or using a torch on a machine that has a hydraulic leak.

FIGURE 22-19 shows a fire hazard warning you may see on a machine.

FIGURE 22-19 Fire hazard warning that could be found on a machine.
Image Provided As Courtesy of John Deere.

Additional Hydraulic Safety Tips

- Release pressure from any accumulator before disconnecting lines.
- Never mix brands of connectors, hoses, or tubes, or otherwise combine hydraulic components with incompatible specifications.
- Never tighten leaking connectors while the system is under pressure.
- Always use hydraulic equipment and tooling for its intended purpose, according to manufacturer's specifications.
- Clean parts with a non-volatile cleaning solution.

► De-energizing a Hydraulic System

S22002

When de-energizing a hydraulic system, several steps should be followed in order to ensure that it is not accidentally re-energized. Anyone affected by the equipment shutdown should first be informed, and then the equipment should be shut down according to normal operating procedures. The power to the equipment should be turned off at the source, and any dedicated lockout devices specific to the system should be utilized. For MORE, this usually means preventing the diesel engine from being started by locking out the starting system.

The system should be de-energized using any bleed valves designed for the purpose (if fitted), and pressure-monitoring devices such as pressure gauges should be used to ensure that the system is safe. Many newer machines incorporate pressure sensors in their hydraulic systems, and system pressure can be read on the machines display or with a connected laptop computer.

Finally, a restart attempt should be made to confirm that all power is off, and a “Do Not Operate” tag secured to the power source, using a nylon cable tie.

To de-energize a hydraulic system, follow the guidelines in **SKILL DRILL 22-2**.

SKILL DRILL 22-2 De-energizing a Hydraulic System

1. Communicate the system shutdown to all affected personnel.
2. Shut down system according to normal operating procedures.
3. Turn off the power at the source.
4. Lock out energy sources, using dedicated lockout devices specific to the system.
5. Release all sources of stored energy, using bleed valves designed for that purpose.
6. Confirm de-energization with pressure gauges.
7. Attempt to restart machine to confirm power is off; return switch to “off” position.
8. Secure tag (“Do Not Operate”) to the power source, using a nylon cable tie.

► Wrap-Up

Ready for Review

- Typically, a diesel engine is used to drive a hydraulic system pump, and the output component is an actuator. Fluid is used to transfer energy.
- Hydraulic systems were incorporated into off-road equipment many years ago to replace mechanical systems that required high maintenance and were hard to control.
- A pump is used to create fluid flow, and the flow is sent to actuators (cylinders or motors), where it is converted to mechanical motion.
- Resistance to fluid flow caused by loads on actuators creates pressure in the system.
- Forces can be multiplied in hydraulic systems by increasing the surface area of the movable surface in the actuator. System pressure that is applied to a larger surface area increases force output.
- Flow in a hydraulic system is measured in units of volume per unit of time (gpm or lpm).
- Pressure is measured in units of weight or force per unit of area (psi or kg/cm²).

- ▶ Pumps create hydraulic fluid flow for the system to use.
- ▶ Actuators receive fluid flow and convert to either linear or rotary motion.
- ▶ Hydraulic systems have several advantages over mechanical systems, such as flexibility, simplicity, and seamless speed control.
- ▶ Some examples of disadvantages of hydraulic systems are fire hazards, high-pressure fluid hazards, and cleanliness requirements.
- ▶ Pascal's law is a fundamental principle for hydraulic systems and states that pressure applied to a fluid in one part of a closed system will be transmitted without loss to all other areas of the system.
- ▶ Bernoulli's principle states that an increase in the speed of a fluid occurs simultaneously with a decrease in pressure or a decrease in the fluid's potential energy, and the inverse occurs in fluid as speed slows.
- ▶ Many different units of measure are used for hydraulic systems, such as psi, gpm, and fps.
- ▶ Pressure in a hydraulic system is created by resistance to fluid flow. The main source is the load on an actuator, but all components in the system will create some resistance to flow.
- ▶ Force is the resulting output of an actuator that has fluid flow directed to it. A cylinder's rod moving is applying a force to what it is connected to.
- ▶ System pressure can be applied to different-sized actuators to create different output forces.
- ▶ Actuator output speed is directly dependent on the rate of flow it receives and the size of the actuator.
- ▶ Atmospheric pressure is the weight of a 1-inch square column of air at sea level and is equivalent to 14.7 psi.
- ▶ Most gauges account for atmospheric pressure and read 0 psi at sea level, but some are called absolute and read 14.7 psi at sea level.
- ▶ Negative pressure (less than atmospheric) should only occur in two places in a hydraulic system (pump inlet and supply side of an actuator if the load overtakes pump supply).
- ▶ Several international bodies maintain standards for hydraulic systems and components, such as ANSI, ASTM, and ISO.
- ▶ To calculate the force a cylinder can create when fluid is delivered to it, you need to know its piston diameter and the pressure being applied to it. $F = P \times A$.
- ▶ The area of a circle can be calculated if you know either the piston diameter or radius, using the formulas $A = \pi r^2$ or $A = (\pi d^2)/4$.
- ▶ Safety concerns related to hydraulic systems include oil injection, trapped pressure, crushing hazards, burns, slips and falls, and fire hazards.

Key Terms

actuator A mechanism that provides force to move a load. It converts fluid flow into either linear or rotary motion.

effective area the area of a piston that fluid pressure can act on to move a load.

flow Hydraulic pumps create fluid flow. The movement of fluid in a hydraulic system is measured in gpm or lpm.

fluid A substance, such as liquid or gas, that flows and easily changes shape.

fluid power an energy transfer system that uses a fluid as its medium.

force multiplication The force advantage that can be gained at the actuator in a hydraulic system.

gallons per minute or liters per minute Two common units of measure used to quantify fluid flow in a hydraulic system.

gas A state of matter characterized by low density, easy compressibility, and a tendency to diffuse readily and uniformly.

hydraulic system An energy conversion system that uses a hydraulic fluid to transfer power output from a prime mover to actuators that perform work.

hydrodynamics The study of hydraulic systems where a high volume of fluid is in motion at a high velocity.

hydrostatics The study of fluid in an enclosed system where the fluid is at rest.

liquid A fluid that has a definite volume, but no shape. Liquid takes on the shape of its container, up to that volume. For most practical purposes, liquid is incompressible.

mechanical advantage The process of using a device to get more output force than the amount of input force, with the trade-off being that the input distance is proportionately longer than the output distance.

output force Resulting force from a linear actuator that comes from the working pressure applied to the surface area of its piston, expressed as pounds, newtons, or kilograms.

Pascal's law The law of physics that states that pressure applied to a fluid in one part of a closed system will be transmitted equally to all other areas of the system.

pounds per square inch or kilograms per square centimeter Two common units of measure used to quantify pressure in a hydraulic system.

pressure The result of resistance to fluid flow.

prime mover The initial source of energy in a system; a machine that transforms energy from thermal, electrical, or pressure form to mechanical form.

pump The component in a hydraulic system that receives power from a prime mover and produces fluid flow.

viscosity The measurement of the resistance of a liquid to shear (the resistance of a fluid to flow at a given temperature).

working pressure The pressure within a hydraulic system while the system is being operated.

Review Questions

1. Mobile heavy equipment machines rely on _____ systems to power and/or control many of the machine's systems.
 - a. electronic
 - b. electrical
 - c. hydraulic
 - d. rotational

2. Hydrodynamics refers to the study of hydraulic systems where a ____ volume of fluid is in motion at a ____ velocity in an enclosed system, and how the fluid acts on the components in that system.
 - a. high, low
 - b. high, high
 - c. low, low
 - d. low, high
3. All of the following are advantages of using hydraulically powered equipment, *except*:
 - a. having fewer exposed mechanical parts that can wear and break down.
 - b. being self-lubricating and compact.
 - c. having no chance of equipment failure.
 - d. relying on multiplication of forces, whereby a small force can control large forces.
4. Pascal's law states that "the pressure applied to a fluid in one part of a closed system will _____ of the system."
 - a. be transmitted without loss to all the other areas
 - b. be transmitted with loss to all the other areas
 - c. not be transmitted to other area
 - d. be transmitted to only another specific area
5. According to Bernoulli's principle, a rise in pressure in a flowing fluid must always be accompanied by a _____ in the speed.
 - a. sudden decrease
 - b. proportionate decrease
 - c. sudden rise
 - d. proportionate rise
6. Whether metric or standard measurement units are used is usually determined by all of the following *except*:
 - a. where the machine was designed.
 - b. where the machine was manufactured.
 - c. where the machine was tested.
 - d. the common measurement system used by the manufacturer.
7. When the flow rate to a linear actuator is increased, rod travel will _____.
 - a. speed up
 - b. slow down gradually
 - c. not be affected
 - d. drop exponentially
8. If a Technician measured system pressure _____, they would read a positive pressure.
 - a. at the pump inlet
 - b. anywhere between a pump outlet and a work port of an actuator
 - c. in an actuator when the load overcomes the oil supplied to it
 - d. the tank outlet for the pump
9. Which is the world's largest developer and publisher of international standards?
 - a. American National Standards Institute
 - b. International Organization for Standardization
 - c. American Society for Testing and Materials
 - d. Joint Industrial Council

10. Which of the following is a good practice?
 - a. Do not release pressure from any accumulator before disconnecting lines.
 - b. Tighten leaking connectors while the system is under pressure.
 - c. Clean parts with a volatile cleaning solution.
 - d. Make sure any component that could move and cause a crushing injury will be mechanically held in place.

ASE Technician A/Technician B Style Questions

1. Technician A says the term used for the component that drives the hydraulic system is "prime mover." Technician B says that a pump is an example of a power output component. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
2. Technician A says pressure in a hydraulic system is created by pump flow. Technician B says forces can be multiplied in a hydraulic system. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
3. Technician A says flow can be measured in psi. Technician B says pressure can be measured in gpm. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
4. Technician A says hydraulic system pumps create pressure. Technician B says hydraulic system pumps create force. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
5. Technician A says Pascal's law refers to pressure in a sealed system. Technician B says Pascal's law refers to the result of changing speed of hydraulic fluid. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
6. Technician A says the output speed of an actuator is dependent on fluid pressure only. Technician B says the output speed of an actuator is dependent on the rate of fluid flowing to it and its size. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
7. Technician A says the retract force from a double-acting cylinder will always be less than the extend force given the same

pressure applied. Technician B says a single-acting cylinder only produces force when it extends. Who is correct?

- a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
8. Technician A says there are only European organizations to oversee technical and safety standards for hydraulic systems. Technician B says there are only American organizations to oversee technical and safety standards for hydraulic systems. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
9. Technician A says that to find a value for force, you need to divide pressure by area. Technician B says to find the value for force, you need to multiply pressure by the area. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
10. Technician A says oil injection injuries can be life threatening. Technician B says trapped oil pressure is always easy to release. Who is correct?
- a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B

CHAPTER 23

Hydraulic Components— Principles of Operations

Knowledge Objectives

After reading this chapter, you will be able to:

- **K23001** Identify different types and applications of hydraulic systems used on mobile off-road equipment.
- **K23002** List the components of a basic hydraulic system.
- **K23003** Explain the operating principles of hydraulic system components.
- **K23004** Describe the operating principles of a basic hydraulic system.
- **K23005** Identify basic hydraulic schematic symbols.

Skills Objectives

After reading this chapter, you will be able to:

- **S23001** Calculate cycle time and horsepower requirements for hydraulic systems.
- **S23002** Draw a hydraulic schematic of a basic circuit using common symbols.

► Introduction

As mentioned in the previous chapter, a hydraulic system is an energy conversion system that begins with the mechanical power output from a rotating prime mover and uses hydraulic fluid to transfer energy to an actuator. The actuator then transfers the energy in the hydraulic fluid back to mechanical energy. The actuator could provide either linear (cylinder) or rotary (motor) motion.

A basic hydraulic system must have a minimum number of components to complete this energy transfer, and this chapter identifies those components and explain their operating principles.

One of the tasks a mobile off-road equipment (MORE) technician performs is diagnosing a hydraulic system problem. To do this, the Technician must be able to read and understand hydraulic schematics. Hydraulic symbols are used to make a hydraulic schematic, and these symbols are identified in this chapter. Another task a Technician may be asked to do is to add or customize existing hydraulic circuits to a machine. This requires reading or making schematics, and this chapter discusses reading and making schematics.

► Types and Applications of Hydraulic Systems Used for Mobile Off-Road Equipment

K23001

Types of Hydraulic Systems

A few different types of hydraulic systems are used on MORE machines. It is important to be able to understand the differences among them.

Open-Loop Hydraulic Systems

Most hydraulic systems used for implement control (blade, bucket, moldboard, etc.) that use linear actuators are considered to be open-loop systems. Open-loop hydraulic systems are ideal for these applications because of the flexibility they allow designers to have when designing hydraulic systems.

In **open-loop** hydraulic systems, the pump supply oil comes from the **reservoir** (tank). The pump then sends it to a directional control valve, where it either returns to the tank or is sent to an actuator. If oil is sent to an actuator, there will be return oil from the actuator that goes back to the tank through the directional control valve. The oil can then go back into the pump inlet. The oil going to the pump always starts at the reservoir and eventually “loops” its way back to the reservoir. The loop is considered to be open because the oil can return to the tank from several sources (directional control valve, actuators, pressure relief valves, etc.). See **FIGURE 23-1** for a schematic of a basic open-loop hydraulic circuit.

Closed-Loop Hydraulic System

In contrast with an open-loop system, in a **closed-loop** system the pump directly feeds a rotary actuator (motor), which negates the need for a directional control valve. The pump outlet sends fluid to the actuator inlet, and the return from the actuator goes directly back to the pump inlet. To reverse direction of the motor, the pump has to reverse flow direction, so it must be a bidirectional pump (to be discussed later). Because of normal internal leakage of the pump and motor, the loop has to be charged (kept full) with oil. A charge pump delivers oil from a reservoir to the closed-loop low-pressure side. Closed-loop hydraulic systems are quite often referred to as hydrostatic systems, and commonly used to generate machine travel. **FIGURE 23-2** shows a closed-loop hydraulic circuit.

Open- and Closed-Center Systems

There are also hydraulic systems that are called open center and closed center. This refers to the type of directional control valve that is used in the system. **Open-center** systems have pump oil flowing through their directional control valves all the time. When the actuators aren't being supplied oil, the pump flow is returned to the tank through the valve. These systems usually have fixed displacement pumps that always pump oil when they are rotating. An open-center directional control valve is depicted in **FIGURE 23-3**.

You Are the Mobile Heavy Equipment Technician

You are given the task of installing a hydraulic attachment on a 40-ton excavator. The machine owner requires a swivel bucket on the machine for a certain job coming up. A swivel bucket has an extra pivot point and uses an extra hydraulic cylinder to make it pivot. The excavator is not plumbed for any attachments, so you will have to install hoses and tubing all the way from the control valve to the end of the stick. It appears as though the main control valve has an extra spool for an attachment, but its outlet ports are blocked off. The owner bought the swivel bucket used, and there are no specifications with it.

1. What information would be helpful to know before starting this job, to ensure proper hydraulic operation of the bucket after it is installed?
2. What information do you need to know in order to buy the correct hoses, tubes, and fittings for the installation?
3. If you found a hydraulic schematic for the excavator, would that help with the install?
4. Once you have the swivel bucket installed, could you expect another type of attachment to work properly if you replaced the swivel bucket with it?

FIGURE 23-1 Schematic of a basic open-loop hydraulic circuit.

FIGURE 23-4 Closed-center directional control valve.

FIGURE 23-2 Closed-loop hydraulic circuit.

FIGURE 23-3 Open-center directional control valve.

Closed-Center Systems

In **closed-center** systems, directional control valves block pump oil flow and only redirect it when there is a request to send oil flow to one or more actuators. These systems are usually used with variable displacement pumps where flow can be shut off when there is no need to move actuators. See FIGURE 23-4 for an example a closed-center directional control valve.

Applications of Hydraulic Systems on Mobile Off-Road Equipment

Common applications for hydraulic systems on MORE are for controlling machine implements such as loader buckets, dozer blades, dozer rippers, and haul truck dump bodies. These systems mainly need the motion and force from linear actuators either to directly move a machine component or indirectly move through a mechanical linkage. FIGURE 23-5 shows a variety of machine implements powered by linear actuators.

There are many other machine systems that need rotary motion such as augers, track drives, and upper structure swing drives. FIGURE 23-6 illustrates machine systems driven by rotary actuators. Rotary actuators produce torque output when oil is delivered to them.

Examples of Hydraulic Systems Found on Heavy Equipment Machines

The following are a few examples of different machines and the functions that hydraulic systems perform on them:

- Cranes—boom lift/lower, winch turning, swing rotation
- Earth movers—bowl lift/lower, ejector forward/back, apron up/down, steering, brakes
- Haul trucks—box lift/lower, steering, brakes
- Pavers—machine travel, belt rotation
- Fork lifts—forks, lower and tilt, steering, brakes
- Aerial lifts—boom lift, travel
- Excavator—boom up/down, stick in/out, bucket open/close, travel

FIGURE 23-5 A variety of machine implements powered by linear actuators.

- Loaders—boom up/down, bucket open/close, steering, brakes
- Compactor—steering, travel, vibration
- Backhoe—front boom up/down, front bucket open/close, rear boom up/down, rear stick in/out, rear bucket open/close, rear boom swing, steering, brakes.

Many machine attachments are hydraulically powered as well, such as hammers, brooms, and clam buckets and can use either linear or rotary actuators.

FIGURE 23-6 Machine systems that are driven by rotary actuators.

► Components of Basic Hydraulic Systems

K23002

To make a basic functional hydraulic system, you would need at least the following components: prime mover, reservoir, pump, directional control valve, pressure relief valve, actuator, hydraulic fluid, filter(s), and fluid conductors.

These components should be matched for both flow and pressure capacity to ensure system efficiency, smooth operation, and maximum longevity. Equipment manufacturer's engineers and designers must design the complete system so that its components work together. To design a hydraulic system, engineers start with determining the needs for actuator output in terms of force output (**linear actuators**) or torque output (rotary actuator) requirements. This determines actuator size and system pressure requirements. Then actuator speed requirements would be established, and this would determine system flow requirements. This includes **rod speed** parameters for linear actuators and output shaft rpm parameters for rotary actuators.

Finally cycle time and stroke length requirements have to be considered for a linear actuator. This also influences maximum flow requirements and, in turn, prime mover horsepower sizing. Hydraulic reservoir sizing could be determined at this point as well.

Mismatching hydraulic system components can lead to inefficiency, poor performance, or premature failures. For example: A pump's output specifications are 10 gpm flow at 2,500 psi while turning at 2,000 rpm. If it was installed into a system that had a working pressure of 3,500 psi, and its linear actuator needed 15 gpm to achieve a minimum **cycle time**, there would be complaints of a slow hydraulic system, and the pump may fail or at least not last for as long as it was originally designed to. If the cycle time is out of specification, the operator will complain that it is too slow or too jerky.

► TECHNICIAN TIP

When diagnosing some hydraulic problems, one of the basic checks to perform is to measure cycle time, that is, the time that a cylinder rod needs to travel one full stroke. A specification in the machine's service information will state what the cycle time should be. The specification will be given in seconds and have a minimum and maximum limit. An example is a bucket cylinder on an excavator that should have a cycle time of 5.5 seconds, extending plus or minus 0.5 second.

The following sections are an introduction to the components required for a basic hydraulic system. Power transfer in a hydraulic system can be understood by looking at **FIGURE 23-7**. The chapters that follow go into more detail about the construction features and types of hydraulic system components as well as how to maintain and repair them.

► Operating Principles of Hydraulic System Components

K23003, S23002

This section will discuss the basic operating principles of MORE hydraulic system components. Many of these components will be thoroughly looked at in chapters that follow. The intent here is to give an introduction to their operation.

FIGURE 23-7 Power transfer in a hydraulic system.

Prime Mover

A machine's prime mover is used for the primary power source for a variety of machine systems, such as drivetrain, electric, and hydraulic.

Almost all MORE uses a diesel engine for their prime mover power. Diesel engines provide high torque and fuel-efficient operation at relatively low rpms, which helps ensure longevity of the components they drive. A diesel engine's high torque and low rpm output works well with most hydraulic systems, but systems that use variable displacement pumps that don't rely solely on pump rpm to determine hydraulic flow output are ideal matches for diesel engines. Pump input rpm can be made to vary from the prime mover rpm by transferring it through a set of fixed ratio gears. A pump drive gear set usually makes the pump turn faster than the prime mover. **FIGURE 23-8** shows a hydraulic pump connected to a prime mover.

Some machines are designed to have their diesel engines run at a steady rpm, but most diesel engine-powered machines normally have an rpm range between 700 rpm and 2,000–2,500 rpm. Depending on the type of pump used, engine rpm has a great influence on pump flow output.

Some large mining equipment, such as drills and shovels, may use electric motors for their prime mover that run at a fixed rpm, whereas some small machines could use gasoline- or propane-powered engines.

Reservoirs

A reservoir is a tank used to store the system fluid. The hydraulic reservoir holds excess hydraulic fluid to accommodate volume changes caused by cylinder extension and contraction, temperature-driven expansion and contraction, and leaks. The reservoir is also designed to aid in separating the air from the

FIGURE 23-8 Hydraulic pump connected to a prime mover.

FIGURE 23-9 A typical hydraulic reservoir.

fluid and to work as a heat exchanger to shed heat from the hydraulic fluid. Heavier contamination particles will also settle out in the bottom of the tank. See **FIGURE 23-9** for a typical hydraulic reservoir.

Reservoirs are usually mounted close to the machines pump(s) to reduce the chance of restricting the pump inlet. They are ideally mounted above the pump so gravity can assist in supplying fluid to the pump, but this may not be possible. The weight of hydraulic fluid above the pump inlet can be used to create “head pressure” to ensure a steady supply of oil gets to the pump.

They are usually fabricated from plate or formed steel, but some smaller machines have plastic hydraulic tanks. Some tanks supply more than one hydraulic system on a machine with the same oil, or they could even be partitioned to contain separate oils. Almost all tanks are constructed with baffles to slow down the return oil flow when it reaches the tank. This helps prevent turbulence in the oil and reduces the chance of air reaching the pump inlet.

Some tanks could have return filters to filter return oil or suction screens to keep large contamination out of the pump inlet.

Hydraulic tanks can be vented or pressurized. **Vented tanks** have breathers on top that allow filtered atmospheric air into them as the oil level changes due to actuator position or heat expansion. **FIGURE 23-10** illustrates a hydraulic tank breather.

FIGURE 23-10 Hydraulic tank breather.

Pressurized tanks take advantage of the pressure caused by expanding oil to create pressure in them. They sometimes use an external pressurized air supply from a pneumatic system or the diesel engine's intake air system to apply pressure to the inside of the tank. Pressurized tanks provide a higher positive pressure to the pump inlet.

Hydraulic tanks almost always provide an easy way for the operator to check the fluid level. Usually this is done by checking a **sight glass** on the side of the tank, but it could also be by using a dipstick. Most new machines also have a sensor that monitors fluid level and/or temperature. **FIGURE 23-11** shows a typical sight glass.

Hydraulic Pumps

A hydraulic pump converts mechanical rotary motion from the prime mover (the electric motor or internal combustion engine) to hydraulic power to operate the system. Hydraulic pumps produce the oil flow that is needed to move actuators (cylinders or motors). See **FIGURE 23-12** for a typical hydraulic pump.

There are two basic categories of hydraulic pump: **nonpositive displacement pumps** (also known as dynamic pumps) and

positive displacement pumps. Pump displacement refers to the amount of fluid that a pump moves or displaces during one rotation of its driveshaft.

You may see a nonpositive displacement-type pump used as a charge pump in a hydraulic system. A charge pump in this case is for “charging” another pump's inlet with oil. Nonpositive displacement pumps have relatively large clearances between the rotating member and their housing and mainly use centrifugal force to move fluid. An engine coolant pump is a good example of this type of pump. Nonpositive pumps are not capable of maintaining high systems pressure because as loads increase, fluid can bypass inside the pump.

Positive displacement-type pumps are used for mobile equipment because they provide flow whenever they are turning and constantly back up the flow of oil leaving the pump. As actuator loads increase and system pressure increases, positive flow is needed to overcome the load and keep the actuator moving. If for some reason the flow of oil from a positive displacement pump gets totally blocked, a catastrophic failure will occur. These pumps must have very close tolerances (between 0.002" and 0.005" is common) between the rotating members inside the pump, as they rely on the fluid viscosity to create a seal between the members. **FIGURE 23-13** portrays a cutaway view of a multi-section hydraulic pump.

► TECHNICIAN TIP

Keep in mind when servicing or repairing hydraulic pumps that they *must* always have an unrestricted supply to their inlet and *must never* have their outlet blocked. If either of these conditions is not met, pump failure will occur. Hydraulic pumps are also highly sensitive to contamination, and great care must be taken to ensure only clean oil enters the pump.

Hydraulic pumps must withstand high pressures and temperatures. Their housings can be made from machined cast aluminum or steel, and their rotating parts inside the housing are machined and hardened steel alloy. Proper clearances are critical to pump efficiency and longevity. As pumps

FIGURE 23-11 A typical hydraulic reservoir sight glass.

FIGURE 23-12 A typical hydraulic pump.

FIGURE 23-13 Cutaway view of a multi-section hydraulic pump.

wear, they become less efficient because less flow is produced per revolution, and this leakage turns into heat.

Pumps used on hydraulics equipment are positive displacement pumps. There are various types of positive displacement pumps—gear pumps, vane pumps, and **piston pumps**. Each type has distinct construction features and operating principles.

Fixed displacement pumps produce the same volume output per revolution, whereas **variable displacement pumps** can vary their output. Gear-type pumps are always fixed displacement-type pumps. For example, if a fixed displacement pump has a displacement of 25 cc/revolution and turns at 1,000 rpm, it will in theory produce a flow rate of 25 lpm. Another pump that has a displacement of 5 cubic inches/revolution and turns at 1,000 rpm will produce a theoretical flow rate of 21.6 gpm. These theoretical calculations don't take into account flow losses that naturally occur and increase with pump wear.

If a variable pump had a maximum displacement of 50 cc/revolution and was turning at 1,500 rpm, the maximum flow rate it could produce at that speed would be 75 lpm. It could also be controlled to produce any flow less than that.

Pump Types

MORE machines use a variety of hydraulic pumps. Several factors influence a manufacturer's decision on which type of pump to use. Some factors are cost, noise limitation, pressure limitations, flow limitations, and expected durability. The following sections discuss the most common pump types found on MORE machines.

Gear Pumps

Gear pumps are the simplest in design because they only contain two moving parts. There are two types of gear pumps: internal gear and external gear. External gear pumps are most common and have two gears with equally spaced teeth on the outside of their shafts that rotate inside the pump. One gear is driven by a splined or keyed shaft, and as it is driven, it drives the second gear inside the pump housing. When the pump starts to rotate, a low pressure is created at its inlet port, and hydraulic oil moves from the tank into the pump. The oil then is carried around the inside of the pump in the space between the teeth on each gear and the inside of the housing. As the oil reaches the pump outlet port, it leaves the pump and enters the system. **FIGURE 23-14** depicts a gear pump disassembled.

Vane pumps

Vane pumps have multiple sliding vanes that are carried around in a rotor driven by the pump shaft. These parts of the pump rotate inside a cam ring that allows the vanes to move in and out of the rotor. As the vanes move, they create a changing volume between them. When a vane passes by the inlet port, oil moves into the pump because of the expanding size of the volume between vanes, which creates a lower pressure than the reservoir. Once the vanes pass the widest part of the cam ring and the volume starts decreasing, the oil is forced out the pump outlet and into the rest of the system. See **FIGURE 23-15** for an

FIGURE 23-14 A gear pump disassembled.

Balanced Vane Pump

FIGURE 23-15 A vane pump rotor and cam ring.

illustration of a vane pump rotor and cam ring. Vane pumps can be balanced (two inlet ports and two outlet ports) or unbalanced and can be fixed or variable displacement.

Piston Pumps

Piston pumps are the most complex type of pump and can be either fixed or variable displacement, which makes them ideal

FIGURE 23-16 The cylinder block, pistons, and swashplate from a piston pump.

for a wide range of applications. This type of pump has a set of pistons that are carried around in a block that is driven by the pump shaft. The pistons have shoes that ride on a swashplate. A fixed displacement pump has a swashplate that is fixed at a certain angle (a few degrees from 90 to the centerline of the shaft). The swashplate angle determines the stroke length, which in turn determines the pump displacement. A variable displacement pump has a movable swashplate. As the swashplate moves, the pump displacement changes. **FIGURE 23-16** illustrates a piston pump's cylinder block, pistons, and swashplate.

Hydraulic Valves

Valves are constructed in a wide variety of configurations to meet different needs within hydraulic circuits. They can be assembled in blocks or modules, or can work alone. Whether used to relieve pressure or to meter hydraulic fluid to actuators, each valve is critical to the operation of all hydraulic equipment. Hydraulic valves can have housings that start out as cast steel or aluminum blocks that are then machine finished. Internal valve components start out as steel alloy materials that are finely machined and finished. Examples of different types of hydraulic valves and their functions include the following.

FIGURE 23-17 Main relief valve that is part of a directional control valve assembly.

Pressure Control Valves

Pressure control valves can limit system pressure or circuit pressure. They are usually adjustable and are set to keep pressures to a safe level to prevent component failure. See **FIGURE 23-17** for a main relief valve that is part of a directional control valve assembly. Normally, pressure control valves are held closed by spring pressure.

Flow Control Valves

Flow control valves control the flow rate of the fluid to the actuators so they operate at the proper speed. Flow control valves can be manually adjusted or actuated by hydraulic oil.

Directional Control Valves

Directional control valves direct the fluid to and from the actuators. Main control valves can have several sections or separate control valves combined into one housing, or they can be standalone components. Pilot control valves are a type of directional valve actuated by joysticks, and direct a much lower pressure oil to a main control valve to control its actuation.

Directional control valves can be controlled manually, electrically, pneumatically, or hydraulically. See **FIGURE 23-18** for an example of a directional control valve that is manually actuated.

SAFETY TIP

If you are required to adjust pressures in a hydraulic system great care must be taken to ensure pressures don't exceed maximum allowable limits. Excessive system or circuit pressures can cause sudden component failure, which can lead to a dangerous high-pressure leak. If a technician is exposed to a high-pressure leak, there is a great risk of an oil injection injury. These injuries are very serious and can lead to death.

Hydraulic Actuators

Actuators convert fluid energy back into mechanical energy to move a load. They can come in two forms: linear actuators (such as hydraulic cylinders, or rams), or rotary actuators (hydraulic motors).

FIGURE 23-18 A directional control valve that is manually actuated.

FIGURE 23-19 A linear actuator on a machine.

Hydraulic Cylinders

Hydraulic cylinders, or rams, receive hydraulic fluid from a directional control valve and transfer fluid in motion into linear mechanical motion. This is why they are called linear actuators. They are used to do everything from steering wheel loaders or lifting dump bodies on haul trucks, to moving the buckets of giant shovels in open-pit mines. In fluid power mechanics, the hydraulic cylinder enables the lifting of heavy components or materials in mobile equipment applications.

Hydraulic cylinders are made up of a barrel, a piston and rod assembly, and a head. The head and barrel make a sealed container in which the piston and rod assembly moves. The barrel is stationary and usually attached to the machine with a steel pin while the end of the rod is attached to a movable component. See **FIGURE 23-19** for a linear actuator on a machine.

There are several variations of linear actuators, such as single acting, double acting, telescoping, and double rod. **Double-acting cylinders** are the most common design. They are sometimes called differential cylinders because their rod takes up space in the cylinder and creates a speed and force differential as the rod moves in and out of the barrel. Oil is directed into the cylinder through one of two ports at opposite ends of the barrel, and this

oil is applied to either side of the piston. The oil flow acts on one side of the piston to move it and the rod, which in turn moves the load. See **FIGURE 23-20** for an illustration of the components that make up a double-acting linear actuator.

All linear cylinders rely on a series of seals to keep fluid from leaking both internally and externally. Barrels start out as steel tubes that are finished internally to a crosshatched pattern with a specified roughness. Barrel bottom ends are usually welded on or threaded on and machined to receive pins. Rod end caps or heads are usually bolted to the barrel. Rods have a chrome finish that can be damaged fairly easily, and the rod end is usually welded to the rod. Pistons can be threaded onto the rod or held on with a large nut or bolt.

Hydraulic Motors and Rotary Actuators

Typically, hydraulic motors provide continuous rotary motion, whereas rotary actuators (sometimes called oscillators) provide a limited rotation, usually up to a maximum of 720 degrees.

A **hydraulic motor**, or actuator, is similar in construction to a hydraulic pump. But whereas pumps convert mechanical rotary motion to hydraulic power, the rotary actuator reverses the process by using the hydraulic power to create rotary

FIGURE 23-20 Double-acting linear actuator components.

mechanical motion. As with pumps, there are many different designs of hydraulic motors in order to best match specific applications. Hydraulic motors are available in fixed and variable displacement configurations and are almost always bidirectional to provide forward and reverse motion. By simply reversing flow to the motor, the output shaft rotation is reversed.

One common application for a rotary actuator is for producing travel torque for either a wheel-type or track-type machine. Another use is to turn the upper structure of an excavator or crane. See **FIGURE 23-21** for rotary actuators that drive the swing mechanism for a large crane.

Some types of hydraulic motors are gear, axial piston, bent axis piston, cam lobe, and gerotor. They all have precision-machined internal components and seals that are susceptible to contamination. Input flow is applied to movable components inside the motor, which in turn creates rotation that is transferred to the motor's output shaft. Most hydraulic motors have three ports to allow fluid movement in and out of them: two work ports and a third port to allow internal leakage to drain. See **FIGURE 23-22** for a cutaway view of a **bent axis motor** with a brake assembly integrated.

FIGURE 23-21 Rotary actuators that drive the swing mechanism for a large crane.

FIGURE 23-22 Cutaway view of a bent axis motor with a brake assembly integrated.

Hydraulic Filters

Filters are an important part of a hydraulic system because they remove damaging contaminants from the hydraulic fluid. Hydraulic systems are very sensitive to any form of **contamination** (liquid, solid, gaseous), and some solid contaminant particles can be microscopic in size. To keep fluid contamination to a safe level, several different styles of filters can be used in hydraulic systems to prevent contamination from damaging internal components. The most common type of filter is one that uses a filter media (mesh, cellulose, or synthetic) to capture contamination. They can be **spin-on-type filters** that are replaced as a unit, or cartridge type that only have the element replaced. See **FIGURE 23-23** for some typical spin-on filters and a cutaway view of a spin-on hydraulic filter.

Filter efficiency refers to how effective the filter's contaminant capture is versus the extent to which it restricts flow. Filter assemblies have a bypass feature that allows flow past the filter if it becomes too restricted because of contaminant loading. Many filter assemblies will alert the operator if the bypass opens.

FIGURE 23-23 Typical spin-on filters and a cutaway view of a hydraulic spin-on filter.

Anytime the bypass for a filter opens, the machine should be stopped safely to prevent system damage.

Contamination can be removed from a hydraulic system by filters located at six different points within the system:

1. **Tank breather filter:** Large volumes of air can move in and out of a hydraulic tank. The air has to be filtered to remove water and dust particles before they contaminate the fluid. In addition, vapors released to the atmosphere from the hydraulic oil have to be removed to prevent air pollution.
2. **Case drain filter:** These are sometimes used to filter internal leakage oil from pumps and motors.
3. **Suction filter:** Suction filters or lines range from a coarse strainer of 250 microns (60 mesh) to a fine element of 25 microns (550 mesh). Suction filters clean the oil before it enters the pump, but they can also restrict flow if they are clogged or if the oil is too thick. Restricting oil flow to a pump will cause damage to it.
4. **Pressure filter:** A pressure filter or line can be installed between the pump and the directional control valves to remove fine particles, down to 3 microns (4,800 mesh) in some systems.
5. **Return filter:** A return filter filters the oil returning to the tank from the valves and actuators. Keeping the fluid in the hydraulic tank clean of contaminants is important so that the contamination doesn't get sent back through the system. See **FIGURE 23-24** for a return cartridge-type filter.
6. **Off-line filter:** The filtration system filters only part of the system's oil flow, so a dedicated pump and filtration system can be installed. Components can be smaller, and the finest of filters can be used without affecting the performance of the main system. These filters are sometimes called kidney loop filters.

FIGURE 23-24 A return cartridge-type filter.

► TECHNICIAN TIP

A common task that a technician will perform on MORE is changing hydraulic filters. When doing this for the first time on a certain type or model of equipment, you should always refer to the maintenance guide for the machine. There could be one or two filters in locations on the machine that are not easy to find. You also need to take care that all pressure is released before removing filters or else you risk creating an environmental or safety hazard. **FIGURE 23-25** depicts an example of a warning found on a machine.

FIGURE 23-25 Warning found on a machine.

Lines and Fittings

Lines and fittings carry the fluid from the reservoir to the pump and on to the remaining system components through a combination of rigid steel tubing and flexible hose assemblies. Lines and fittings are also sometimes called **fluid conductors**.

When working with hoses and tubes, it is particularly important to understand how hoses are made, how they are fitted, and what their ratings mean. Flexible hose assemblies allow movement of actuators, reduce the transmission of vibrations, and absorb pressure spikes better than comparable rigid steel tubing. A hydraulic hose is constructed from layers of material selected to meet the required operating pressure and to be compatible with hydraulic fluids and applications. Hoses and tubes used on an excavator are shown in **FIGURE 23-26**.

Rigid steel tubes assist in cooling the fluid, are cost effective, and take up less space than comparable flexible hoses. The size of the internal bore of the tube or hose is important in facilitating the efficient flow of the hydraulic fluid. If the internal diameter is too small, then the flow will be restricted and will become turbulent. This also leads to excessive heat buildup in the fluid, which increases inefficiency. The correct internal diameter creates a smooth flow, described as **laminar flow**. Although desirable, laminar flow is often difficult to achieve in mobile hydraulic systems.

To achieve a constant oil flow rate within a circuit, three different factors have to be considered:

1. The supply from the tank or reservoir to the pump is subject to very low pressures and requires a large internal diameter to allow free flow of oil to the pump inlet.

FIGURE 23-26 Hoses and tubes used on an excavator.

2. Tubes or hoses subject to high pressure can be considerably smaller in diameter than pump supply hoses and will still maintain laminar flow.
3. Fluid returning from the directional valves to the tank or reservoir is subject to an intermediate pressure and requires an intermediate diameter.

Hydraulic fittings come in a wide variety of styles, types, pressure ratings, and sizes. As with hoses and tubes, great care must be taken when replacing fittings to ensure they are rated for the pressure they will be exposed to. They must also be compatible with the hoses and fittings they are connecting, or sudden failure is quite possible. See **FIGURE 23-27** for a variety of hydraulic fittings.

When replacing a hose or tube, it is always best to go with an original specification part or an oversize part, if unsure. Required pressure ratings for hoses and tubes must always be matched or exceeded when replacing hoses or tubes. **FIGURE 23-28** illustrates hoses marked with specifications and ratings.

FIGURE 23-27 A variety of hydraulic fittings.

FIGURE 23-28 Hoses marked with specifications and ratings.

Some other components that may be found in hydraulic systems, but that are not necessary for all systems, are accumulators, heaters, and coolers.

Accumulators

A hydraulic **accumulator** is capable of storing hydraulic energy. It can perform a number of functions when used in a hydraulic system, including the following:

- Acting as an emergency power source in the event of pump or engine failure
- Providing a pressure source to hold loads in place with the pump shut down
- Providing additional hydraulic energy during peak load demand and recharging during low-demand periods, just like a battery and alternator in a car
- Removing pressure and flow pulsations created by actuators or pumps
- Providing fluid flow to supplement the pump in order to increase actuator speed
- Acting as a shock absorber for an actuator (an accumulator can operate faster than a relief valve)
- Operating as part of a suspension system for a vehicle or machine
- Starting up an emergency lubrication system
- Acting as part of an engine starting or cranking system for marine or mining applications.

A hydraulic fluid cannot be compressed or changed chemically. Therefore, for a hydraulic accumulator to work, the hydraulic energy must be changed into mechanical or pneumatic energy.

There are three types of hydraulic accumulators; each accomplishes energy storage in a different way:

- **Weighted accumulators** make use of a hydraulic cylinder lifting a weight, either directly or through a lever. The weight acts on the fluid, and the energy stored can be retrieved when needed. These are rarely found on today's machines.
- **Spring-loaded accumulators** replace the weight with a spring, usually the coiled compression type. Using a spring

FIGURE 23-29 Examples of hydraulic accumulators.

FIGURE 23-30 A hydraulic cooler.

reduces the physical size of the accumulator assembly. This type of accumulator is not very common.

- **Compressed-gas accumulators**, also known as hydro-pneumatic accumulators, replace the coiled spring with a gas. Oxygen or air is not suitable, as it may cause combustion, but nitrogen, which is almost inert in its natural diatomic state, is commonly used.

See **FIGURE 23-29** for Examples of hydraulic accumulators.

Heaters and Coolers

Heaters and coolers help to regulate hydraulic fluid temperature. These **heat exchangers** either put heat into the hydraulic fluid or remove it. To maintain fluid temperatures within the required operating range, an oil cooler may be required to dissipate waste heat that is generated by the hydraulic system. The quantity of waste heat increases as the components wear; therefore, the maintenance of the cooling circuit becomes more important as running hours accumulate on hydraulic components.

Two types of oil coolers can be found on MORE:

- The liquid-cooled type, usually used in torque convertor systems and marine applications

- The air-cooled variant, the most common in mobile equipment for hydraulic systems.

Air-cooled hydraulic oil cooler circuits operate with a design similar to that in an engine cooling system. Oil is circulated through small tubes with fins that dissipate heat to the surrounding air. A fan is used to keep air flowing past the cooler. See **FIGURE 23-30** for a hydraulic cooler.

More elaborate systems can feature a thermostatic or pressure-based bypass valve that directs cold fluid directly to the reservoir. As fluid temperature rises and viscosity reduces, a greater volume of fluid is passed through the cooler.

Hydraulic fluid heaters are found on machines that work in extreme cold environments and are used to maintain a minimum oil temperature and viscosity. They can be diesel-fired heat exchangers similar to supplementary engine coolant heaters or electric elements that could use a generator to keep them warm.

Identifying and Locating Hydraulic Component of MORE

To identify and locate hydraulic components on MORE, follow the steps in **SKILL DRILL 23-1**.

SKILL DRILL 23-1 Identifying and Locating Hydraulic Components on MORE

1. Go to one piece of MORE, and perform the required LOTO procedures to be sure the machine is in a de-energized state. Record the make, model, and hours on the machine.
2. If necessary, carefully open or remove access panels, to view hydraulic system components.
3. Locate the following hydraulic components on the machine: prime mover; pump; reservoir; directional control valve; one actuator; and one filter.
4. Describe the location of each component in relation to front/back, left/right of the machine and other machine components.
5. Give a brief description of each component.
6. Is the system an open-loop or closed-loop hydraulic system?
7. Are there any other hydraulic components on the machine, such as accumulators or heater/coolers?
8. Are there any safety warnings on the machine related to the hydraulic system?
9. Replace or close all access panels on the machine.
10. Remove all LOTO devices.

► Operation of a Basic Hydraulic System

K23004

A good example of a simple basic hydraulic system complete with prime mover is a hydraulic **wood splitter** powered by a gasoline engine. See Figure 23-30 for a typical gasoline-powered wood splitter. Although a wood splitter isn't considered to be a mobile off-road machine, its hydraulic system makes a great representation of a single circuit hydraulic system that could be found on MORE.

A wood splitter is used to split round 16–24" lengths of wood into smaller pieces, for firewood, that are easier to handle (FIGURE 23-31). It has one circuit or function. A wedge is attached to the end of the rod of its double-acting cylinder, and as the wedge gets pushed into the piece of wood that is held stationary, the wedge splits it.

A typical wood splitter produces 20 tons of linear force, good enough to split most hardwood easily. It uses a 6–8 horsepower prime mover that runs at a steady rpm, and therefore the pump supplies a steady flow to the circuit. The small gasoline engine drives a pump through a coupler. The pump is supplied oil from a reservoir to its inlet and sends oil to a directional control valve. The pump is a fixed displacement gear-type pump, which means as long as it is turning, it is moving oil, and the rate of oil flow is dependent on rpm.

FIGURE 23-31 A typical gasoline-powered wood splitter.

► TECHNICIAN TIP

Most wood splitters use a two-stage pump (one that has two sections) that delivers flow from both sections to the actuator when there is no load on it for faster actuator movement. There is an unloader valve in the pump that redirects flow from one of the sections back to the pump inlet when system pressure increases. This occurs when the wedge moves into the log. To keep things simple for now, we will assume the pump is a single-stage or single-section type. See FIGURE 23-32 for a two stage pump. If you are not familiar with how a wood splitter operates, simply search the Internet to find a video of one at work. Keep in mind that there are many variations of these machines, so try to look for a simple single-function wood splitter.

FIGURE 23-32 Typical two-stage pump.

The directional control valve is an open-center type, which means when it's in neutral, it allows pump flow to pass through it and return to the tank through a filter. However, as soon as the operator moves the lever for the valve, its spool shifts and pump flow is redirected to the actuator. Pump flow now moves the piston in the cylinder, and the rod that is attached to the piston moves. Oil on the other side of piston also has to move, and it is returned back to the tank through the control valve. It passes through the return filter before it gets to the tank. For any open-loop hydraulic circuit that uses a fixed displacement pump, this is a typical path for the oil to circulate.

Just like any hydraulic system, pressure in the system is dependent on the load on the actuator. If the rod is moving out without any resistance, then pressure will be very low. If a log is placed on the bed and the operator keeps the lever shifted to move the rod and split the wood, then pressure will rise in an amount directly proportional to how much resistance the piece of wood creates. For example, a piece of soft wood may only require 1,000 psi to keep the rod moving, but a knotty piece of hardwood may stall (stop moving) the rod. If this happens, the pressure relief valve must open or else the engine would stall. When the pressure relief valve opens, the fluid continues flowing to the reservoir, and the engine keeps running, although it will be under maximum load.

To reverse the direction of the wedge once a piece of wood is split, the operator moves the lever on the directional control valve in the opposite direction. The spool inside the valve shifts, and pump oil is directed to the rod end of the cylinder. Oil now acts on the rod side of the piston and forces the piston and rod back into the cylinder. Once the wedge is drawn back, another piece of log can be placed on the table to be split by the next rod stroke.

The speed at which the rod moves is dependent on the amount of oil flow sent to it by the pump. Rod speed is measured in ft/sec or m/sec. Pump output is measured in gpm (gallons per minute) or lpm (liters per minute).

Oil pressure acting on the cylinder is dependent on the amount of resistance the rod encounters. Maximum pressure is limited by the pressure relief valve that is in the directional control valve.

► Calculating Cycle Times and Hydraulic Horsepower

S23001

If we use the above example of the wood splitter, we can take a look at how much horsepower is required to drive the pump and how fast the rod can cycle. Cycle time refers to the time it takes a cylinder rod to move a full stroke either extending or retracting.

To calculate cycle time, you need to know a few values. First, you have to know the cylinder dimensions to be able to calculate the volume of oil needed to move the rod a full stroke.

Once cylinder volume is determined and pump flow is known, cycle time can be calculated.

FIGURE 23-33 Dimensions of the cylinder.

Example 1

See FIGURE 23-33 for an illustration showing the dimensions of the cylinder.

If a wood splitter has a cylinder with a piston diameter of 4" (radius is 2"), a rod diameter of 2" (radius is 1") and a stroke of 24", what is the volume of oil needed to cycle the rod?

Volume of head end of cylinder
(volume below piston when it's fully extended) = $A \times L$

$$\begin{aligned} \text{Area of piston} &= \pi r^2 \\ &= 3.14 \times 2^2 \\ &= 12.56 \text{ in.}^2 \end{aligned}$$

$$\begin{aligned} \text{Volume of cylinder below piston} &= A \times L \\ &= 12.56 \text{ in.}^2 \times 24" \\ &= 301.44 \text{ in.}^3 \end{aligned}$$

Therefore, it would take just over 300 in.³ of oil to fully extend the rod from the fully retracted position.

To calculate the volume of oil needed to retract the rod from fully extended, the volume that the rod takes up must be subtracted from the volume above the piston.

Volume of rod = $A \times L$

$$\begin{aligned} A &= \pi r^2 \\ A &= 3.14 \times 1^2 \\ A &= 3.14 \text{ in.}^2 \end{aligned}$$

$$\begin{aligned} V &= A \times L \\ V &= 3.14 \text{ in.}^2 \times 24" \\ V &= 75.36 \text{ in.}^3 \end{aligned}$$

$$\begin{aligned} \text{Volume of oil needed to retract piston fully} &= \\ \text{Total volume above piston—rod volume} &= \\ &= 301.44 \text{ in.}^3 - 75.36 \text{ in.}^3 \\ &= 226.08 \text{ in.}^3 \end{aligned}$$

If the pump produces 10 gpm, how fast would the rod fully extend?

$$\text{Cycle time extend} = \text{Volume of oil needed} / \text{Pump flow} \times 60$$

Because the units must be the same to find an answer, you first need to convert oil volume from in.³ to gallons. There is 231 in.³ per U.S. gallon of oil.

$$\begin{aligned}\text{Volume (gallons)} &= \text{Volume (in.³)} / 231 \\ &= 301.44 / 231 \\ &= 1.3 \text{ U.S. gallons}\end{aligned}$$

$$\begin{aligned}\text{Cycle time extend} &= 1.3 \text{ gallons} / 10 \text{ gpm} \times 60 \\ &= 7.8 \text{ seconds}\end{aligned}$$

$$\text{Cycle time retract} = \text{Volume of oil needed} / \text{Pump flow} \times 60$$

$$\begin{aligned}\text{Volume (gallons)} &= \text{Volume (in.³)} / 231 \\ &= 226.08 \text{ in.³} / 231 \\ &= 0.98 \text{ gallons}\end{aligned}$$

$$\begin{aligned}\text{Cycle time retract} &= 0.98 \text{ gallons} / 10 \text{ gpm} \times 60 \\ &= 5.9 \text{ seconds}\end{aligned}$$

The difference in cycle times from extend to retract is roughly 1.9 seconds. This is because the volume that the rod takes up is not needed to move the piston. See **FIGURE 23-34** for an illustration of the example.

To calculate how much theoretical horsepower is needed to drive a pump, you need to know the maximum pressure the system is limited to and the maximum flow output of the pump. The formula for calculating hydraulic horsepower is $\text{psi} \times \text{gpm} / 1,714$.

$$\begin{aligned}\text{Hydraulic horsepower} &= \text{psi} \times \text{gpm} / 1,714 \\ &= 3,000 \text{ psi} \times 10 \text{ gpm} / 1,714 \\ &= 17.5 \text{ hp}\end{aligned}$$

FIGURE 23-34 Cycle times.

TECHNICIAN TIP

Hydraulic systems are generally about 85% efficient, which means that the output energy value is only 85% of the input energy value. The 15% loss is mainly due to heat loss, which is a result of friction created by fluid flowing through the system. Friction creates heat, which in a hydraulic system is wasted energy because it simply dissipates to the atmosphere and performs no work.

For example, the wood splitter above requires a theoretical 17.5 hp prime mover based on a given flow output and the system's pressure. However, due to flow losses (inefficiencies), we will assume the system is only 85% efficient; therefore, it will actually require slightly less than 15 hp to drive the pump.

Prime Mover Requirements

As mentioned previously, most wood splitters use a two-section pump that diverts part of the pump flow when the system pressure increases. It uses a pump unloader valve to do this, but why is this feature used?

If pump flow at high pressure is reduced, the prime mover can be downsized, and instead of needing a 17.5 hp gasoline engine to drive the pump, a much smaller prime mover is needed. Also, for better machine operation if the rod slows down when the load increases, the operator will have better control.

Therefore, if half of the pump flow is diverted when pressure increases, then the prime mover size would decrease by one-half.

$$\begin{aligned}\text{Hydraulic horsepower} &= \text{Flow} \times \text{pressure} / 1,714 \\ &= 5 \text{ gpm} \times 3,000 \text{ psi} / 1,714 \\ &= 8.75 \text{ hp}\end{aligned}$$

System Pressure Requirements

To calculate the maximum pressure at which the wood splitter needs to operate in order to produce 20 tons of force, you only need to know the piston area. Because $\text{Force} = \text{Pressure} \times \text{Area}$, this can be easily calculated by reworking the formula:

$$\begin{aligned}F &= P \times A \\ P &= F / A \\ P &= 20 \text{ tons} / 12.56 \text{ in.²} \\ P &= 40,000 \text{ lb} / 12.56 \text{ in.²} \\ P &= 3,185 \text{ psi}\end{aligned}$$

Therefore, if the relief valve was set at 3,200 psi, the wood splitter could produce approximately 20 tons of force on extend.

Calculating Cycle Times

To calculate cycle times, follow these steps:

1. Determine cylinder extend volume: $\text{Piston area} \times \text{Stroke length}$
2. Calculate cycle time for extend: $\text{CT} = \text{Extend volume} / \text{pump flow} \times 60$

3. Determine cylinder retract volume: Effective area $\times$ Stroke length
4. Calculate cycle time for retract: $CT = \text{Retract volume} / \text{pump flow} \times 60$.

Example 1

A cylinder has a piston diameter of 20 cm, a rod diameter of 10 cm, and a stroke of 100 cm. What are the extend and retract times if a pump supplies 50 lpm to the cylinder?

Example 2

A cylinder has a piston diameter of 6.4", a rod diameter of 4.2" and a stroke length of 17". What are the extend and retract times if a pump supplies 28 gpm to the cylinder?

Calculate the hydraulic horsepower the following systems produce:

► Basic Hydraulic Schematic Symbols

K23005

Technicians who service and repair MORE will at some point need to read and understand a **hydraulic schematic**. This could be to assist with diagnosing a hydraulic system problem or to help with connecting a hydraulic attachment to a machine. Hydraulic schematics are similar to electrical schematics in that standard graphic symbols are used to represent machine components; they are not accurate as far as spatial relationship, and they can sometimes be color-coded. Hydraulic schematics can be used to trace oil flow through a system and to see what components are part of either one circuit or the entire system.

Schematics can come in paper or electronic formats. It's very important to find the exact schematic for the machine you are looking for because hydraulic systems can change drastically from one machine model to another, and even between machines that are of the same series production.

Look at **FIGURE 23-35** to see a schematic representation of the wood splitter that was discussed previously. This is a very simple schematic and very easy to interpret. More complex

FIGURE 23-35 Schematic for a typical wood splitter.

multi-circuit hydraulic systems could have their hydraulic schematics spread over several pages and have many more complex symbols.

The graphic symbols for fluid power systems and components, and the terms used to describe them, are standardized throughout the world by the ISO, with additional input from the ANSI.

Some manufacturers may use slight variations of these symbols, but they should be recognizable as symbols for the components they are representing.

Some basic shapes are the starting point for symbols used to identify hydraulic components such as the ones listed here:

Circle—pump or motor

Square—valve

Rectangle—multi-position valve or linear actuator

Diamond—fluid conditioner

Lines—hoses or tubes

Oval—accumulator

Additions to these basic symbols make up the majority of common hydraulic symbols. One common symbol that can be used with many other component symbols is a spring symbol, which is simply a series of horizontal or vertical zigzag lines. Chapter 33 for more details on hydraulic symbols and schematics.

Pumps and Motors

The symbols for pumps and motors start with a circle to indicate rotary motion. Triangles are added, and their orientation indicates fluid flow direction, which in turn shows whether it is a pump or motor. Solid triangles indicate fluid pumps (hydraulic pumps), and hollow triangles indicate a pneumatic pump (air compressor). Two triangles in a circle indicate a bidirectional component. A diagonal arrow through the symbol denotes that the component is a variable displacement type. Otherwise, you would assume it is fixed displacement. See **FIGURE 23-36** for the common symbols for pumps and motors. Two or more circles that are together indicate a multi-section pump.

FIGURE 23-36 Common symbols for pumps and motors.

Valves

Valve symbols start with a square box, and as lines, arrows, and spring symbols are added, the type of valve is indicated. They will be shown in their unactuated, or at rest, state (machine off).

Pressure and Flow Control Valve Symbols

Common single box symbols are pressure relief valves, flow control valves, and pressure reducing valves. A square box will have other lines and arrows added to it to indicate how the valve functions. See **FIGURE 23-37** for some examples of pressure and flow control valves.

Directional Control Valve Symbols

Directional control valves are drawn as more than one square box joined together. The number of boxes indicates how many positions the valve can be in, and lines drawn parallel to the boxes indicate whether the valve is variable. The most common directional control valves have two, three or four positions.

The number of ports the valve has is shown by lines connected to one of the valve boxes, demonstrating the number of ways that oil can flow in and out of the valve body. Usually this is the “neutral position” for the valve, or the position when it is not being actuated.

Symbols will also be added to the ends of the valve to indicate how the valve is actuated (manually, electrically, pneumatically, or hydraulically).

A very common directional control valve is the three-position, four-way valve. **FIGURE 23-38** shows the symbol for a three-way, four-position, hydraulically actuated directional control valve.

Linear Actuator Symbol Symbols

Schematic symbols for linear actuators (cylinders) are rectangular in shape, with two lines at 90 degrees to each other, indicating the rod and the piston. A single-acting cylinder has just

FIGURE 23-37 Examples of pressure and flow controls valves.

FIGURE 23-38 A three-way, four-position, hydraulically actuated directional control valve.

FIGURE 23-39 Common linear actuator symbols.

one port, and a double-acting cylinder has two. One variation of a basic cylinder symbol includes a cushioning cylinder. See **FIGURE 23-39** for common linear actuator symbols.

Fluid Conditioner Symbols

The basic shape used to represent fluid conditioners (filters, screens, heaters, and coolers) is a diamond. Lines and triangles are added to the diamond to indicate whether it is filtering, heating, or cooling oil that flows through it. **FIGURE 23-40** gives symbols for fluid conditioners.

Hydraulic Line Symbols

MORE has a wide variety of hydraulic hoses, tubes, and fittings to route hydraulic oil to and from all the hydraulic components on the machine. If you look at a hydraulic schematic, you will get the impression that most hydraulic lines are the same. To simplify a schematic, almost all hydraulic lines are drawn with two or three different symbols. Some schematics may include colored line symbols to indicate pressure or return lines, but most use black coloring for all lines. Lines that connect can be indicated by a dot where they cross. See **FIGURE 23-41** for a few examples of common symbols used for lines. Generally speaking, solid lines indicate pressure lines; dashed lines indicate pilot pressure lines; and dotted lines indicate drain lines. However, MORE manufacturers use a wide variety of line symbols.

Other Hydraulic Symbols

Some less common symbols you may see on a hydraulic schematic can be used to represent components such as accumulators, check valves, orifices, switches, gauges, couplers, and enclosures. See **FIGURE 23-42** for some other less common hydraulic symbols.

FIGURE 23-40 Symbols for fluid conditioners.

FIGURE 23-41 Common symbols used for lines.

FIGURE 23-42 Other less common hydraulic component symbols.

MORE Hydraulic System Schematics

FIGURE 23-43 shows one section of a schematic for the hydraulic system of an excavator, as well as more schematic symbols. There are a variety of different symbols representing different components. Can you tell what components each of the symbols represents?

Some tasks may require a MORE technician to draw a hydraulic schematic. This could be for diagnosing problems or for installing hydraulic attachments on machines. **SKILL DRILL 23-2** gives you some practice drawing a hydraulic schematic.

Use of a pencil and ruler is recommended, and when finished, you should be able to trace oil flow through the system as if it were operating. Although there are many approaches to drawing circuit diagrams, very general step-by-step guidelines are provided in the following procedure. Add detail to the directional control valve.

FIGURE 23-43 One section of an excavator schematic and more examples of symbols.

FIGURE 23-43 (Continued)

SKILL DRILL 23-2 Drawing a Hydraulic Schematic of a Basic Circuit Using Common Symbols

1. Start with the pump symbol connected to the reservoir.

2. Add the pressure line from the pump outlet.

3. Show a relief valve attached to the pressure line.

4. Draw directional control, flow control, and any pressure control valves as they should appear in the actual operating circuit to achieve the desired operation of the circuit.

5. Draw the actuator(s).

Wrap-Up

Ready for Review

- ▶ In an open-loop hydraulic system, the pump's oil supply originates at the reservoir, and pump flow eventually returns to the reservoir.
- ▶ In a closed-loop hydraulic system, the pump directly feeds a rotary actuator (motor), which negates the need for a directional control valve.
- ▶ In a closed-center hydraulic system, pump oil is blocked at the directional control valve. These systems are usually used with a variable displacement pump.
- ▶ Open-center systems have a directional control valve that allows pump flow through them.
- ▶ MORE uses hydraulic systems to generate linear or rotary forces and can be used to power many different functions such as lift booms, tilt buckets, steer machines, turn belts, turn fans, and turn winches.
- ▶ Hydraulic system components must be matched for flow and pressure capacity so they work together with smoothness and efficiency.
- ▶ Cycle time is a measure of a linear actuator's rod travel for a full stroke.
- ▶ A hydraulic system needs a prime mover to power it, and the most common type for MORE is a diesel engine. An electric motor could also be used.

- ▶ A reservoir is a tank used to store the system fluid. Reservoirs can be made of plate steel or plastic and are usually mounted close to the pump.
- ▶ Vented tanks allow atmospheric air to move in and out of them.
- ▶ Pressurized tanks are sealed and have a positive pressure in them to assist delivering oil to the pump inlet.
- ▶ Most tanks have a sight glass for the operator or technician to easily check fluid level.
- ▶ Nonpositive displacement-type pumps have relatively large clearances between the rotating member and the pump housing, and mainly use centrifugal force to move fluid.
- ▶ Positive displacement pumps are ideal for hydraulic systems because they provide a positive flow to the system.
- ▶ Hydraulic pumps are made from machined cast aluminum or steel and must be strong enough to withstand high system pressures and temperatures.
- ▶ There are various types of positive displacement pumps: gear pumps, vane pumps, and piston pumps.
- ▶ Fixed displacement pumps produce the same amount of flow for each revolution. The only way to change the flow rate of this type of pump is to change its rpm.
- ▶ Gear pumps are simple fixed displacement pumps with two moving parts: input shaft drives an external gear, which drives a second gear. Oil is carried around the inside of the pump housing.
- ▶ Vane pumps have multiple sliding vanes that are carried around in a rotor that is driven by the pump shaft.
- ▶ Piston pumps are the most complex type of pump and can be either fixed or variable displacement. A series of piston are carried around in a block, and an angled swashplate creates a pumping effect and determines pump displacement.
- ▶ Hydraulic valves are constructed in a wide variety of configurations to meet different needs within hydraulic circuits.
- ▶ Pressure control valves are used to manage pressure levels in hydraulic circuits or systems.
- ▶ Flow control valves control the flow rate of the fluid to the actuators so that they operate at the proper speed.
- ▶ Directional control valves direct the fluid to and from the actuators.
- ▶ Actuators convert fluid energy back into mechanical energy to move a load.
- ▶ Hydraulic cylinders receive hydraulic fluid from a directional control valve and transfer fluid in motion into linear mechanical motion.
- ▶ Linear actuators main components are barrel, head, piston, rod, and seals.
- ▶ Hydraulic motors receive oil from pumps or directional control valves and convert fluid flow into rotary motion; they can reverse direction if flow direction is reversed to them.
- ▶ Hydraulic motors can be fixed or variable displacement.
- ▶ Some types of hydraulic motors are gear, axial piston, bent axis piston, cam lobe, and gerotor.
- ▶ Filters are necessary to keep damaging contamination out of hydraulic fluid.
- ▶ There are several types of filters, such as tank breathers, return filters, and pressure filters.
- ▶ All system pressure must be released before changing hydraulic filters.
- ▶ Lines and fittings connect all system components and must be sized to allow smooth (laminar) flow.
- ▶ Hoses allow movement between movable and stationary components.
- ▶ Hydraulic fittings come in a wide variety of styles, types, pressure ratings, and sizes.
- ▶ All replacement lines and fittings have to be proper pressure rated and proper internal size.
- ▶ Accumulators can store hydraulic energy and are used for a variety of purposes in hydraulic systems. Three different types of accumulators are weighted, spring loaded, and pneumatic.
- ▶ Heaters and coolers are used to regulate fluid temperature.
- ▶ A basic hydraulic system must have the following minimum components: reservoir, pump, directional control valve, actuator, and filter.
- ▶ A wood splitter is a small gasoline-powered hydraulic machine that represents a simple hydraulic system.
- ▶ Cycle time is the amount of time it takes for a cylinder rod to travel one full stroke and is calculated with the formula: Control time = Volume of oil needed/Pump flow $\times$ 60.
- ▶ Hydraulic horsepower is a measure of the power a hydraulic system creates and is calculated with the formula $Hp = \text{psi} \times \text{gpm} / 1,714$.
- ▶ A hydraulic schematic is a graphic representation of a hydraulic system or circuit.
- ▶ Hydraulic symbols represent different hydraulic components and start with basic shapes such as circles, squares, rectangles, and triangles.

Key Terms

accumulator Hydraulic energy storage device.

bent axis motor One type of hydraulic motor that has a set of pistons and cylinder block inside it that receive oil flow and create torque.

closed center Hydraulic systems that have directional control valves that block pump oil flow.

closed loop A classification of a hydraulic system that has the pump outlet oil flowing directly to an actuator inlet.

contamination A damaging substance in hydraulic fluid.

cycle time A measure of the time it takes a cylinder rod to travel one full stroke.

directional control valves Direct the fluid to and from the actuators.

double-acting cylinders Most common type of cylinder, has a rod that can be powered both ways.

filters Component that removes damaging contaminants from the hydraulic fluid.

fixed displacement pumps Produce the same volume of flow per revolution.

fluid conductors Another term for tubes, hoses, and fittings that hydraulic system fluid flows through and that connects components.

flow control valves Control the flow rate of the fluid to the actuators so they operate at the proper speed.

gear pumps Two types—internal and external; external gear hydraulic pumps.

heat exchanger Heaters and coolers found in hydraulic systems.

hydraulic cylinder, or ram A device that uses hydraulic fluid flow and converts it to linear mechanical movement.

hydraulic motor Creates rotary motion when it receives oil flow.

hydraulic schematic A paper or electronic drawing that uses symbols to represent components; together they represent a machine's hydraulic system.

laminar flow Term used to describe smooth, nonturbulent flow.

linear actuators Receive oil from the directional control valve and convert oil flow into linear motion.

nonpositive displacement Types of pumps that have loose-fitting internal components and use centrifugal force to move fluid at low pressure.

open center Hydraulic systems that have pump oil flowing through their directional control valves all the time.

open loop A classification of a hydraulic system that has its pump inlet oil come from the reservoir, and all system flow returns to the reservoir.

piston pumps The most complex type of pump, and can be either fixed or variable displacement. Swashplate angle determines pump displacement.

positive displacement pumps Hydraulic pumps that have close internal clearances and will always move oil when they are turning.

pressure control valves Used to manage pressure levels in hydraulic circuits or systems.

pressurized tank Hydraulic tank that has positive internal pressure.

reservoir A tank used to store the system fluid.

return filter A filter used to clean oil before it returns to the tank.

rod speed A measure of how fast a linear actuators rod moves. Usually measured in fps (feet per second) or mps (meters per second).

sight glass A feature of a hydraulic tank to visually check fluid level.

spin on-type filters One-piece filter assembly.

spring-loaded accumulator A type of hydraulic fluid energy storage device that uses a spring to provide mechanical energy.

vane pumps Have multiple sliding vanes that are carried around in a rotor that is driven by the pump shaft.

variable displacement pumps A type of pump that can vary its displacement independently of its shaft speed.

vented tank Hydraulic tank that allows atmospheric pressure in; it uses two external gears to move oil around the inside of the pump housing.

wood splitter A gasoline-powered hydraulic machine that is used to split round pieces of wood into smaller pieces for firewood.

Review Questions

- Mobile off-road equipment systems mainly need the motion and force from _____ actuators to move a machine component either directly or indirectly through a mechanical linkage.
 - oscillator
 - linear
 - rotary
 - frequency
- Four technicians (Tech A, Tech B, Tech C, and Tech D) decide to build a basic functional hydraulic system. Tech A gathers prime mover, reservoir, and pump. Tech B gathers directional control valve, pressure relief valve, and actuator. Tech C gathers hydraulic fluid, filter(s), and fluid conductors. Tech D gathers relay, electric motor, lithium-ion battery, soldering machine, and soldering lead. Which technician's materials are required to build a functional hydraulic system?
 - Tech A, B, and C
 - Tech A and B
 - Tech D, C, and B
 - Tech A, B, C, and D
- What is cycle time?
 - Time that a piston takes to complete one stroke
 - Time taken to complete one full cycle of fuel intake
 - Time that a cylinder rod needs to travel one full stroke
 - Time that a linear rod needs to travel one round
- Diesel engines provide _____ torque and fuel-efficient operation at relatively _____ rpm's, which helps ensure longevity of the components they drive.
 - high, high
 - high, low
 - low, high
 - low, low
- What is the normal rpm range for most diesel engine-powered machines?
 - 500–2,500 rpm
 - 700–2,500 rpm
 - 800–2,000 rpm
 - 600–2,000 rpm
- In a hydraulic cooler, a thermostatic or pressure-based bypass valve directs cold fluid directly to the reservoir. As the fluid temperature _____ and viscosity _____, a greater volume of fluid is passed through the cooler.
 - rises, increases
 - rises, decreases
 - drops, increases
 - drops, decreases

7. Which of the following is *not* true with respect to a wood splitter?
 - a. The small gasoline engine drives a pump through a coupler.
 - b. The pump is a fixed displacement gear-type pump, which means as long as it is turning, it will be moving oil, and the rate of oil flow is dependent on rpm.
 - c. The pump is supplied oil from a reservoir to its inlet and sends oil to a directional control valve.
 - d. A loader valve in the pump directs flow from the pump inlet back to one of the systems when air pressure decreases.
8. Some basic shapes are the starting points for symbols used to identify hydraulic components. Which of the following symbol and hydraulic component are correctly matched?
 - a. Square—valve
 - b. Diamond—pump or motor
 - c. Oval—hoses or tubes
 - d. Circle—fluid conditioner
9. Two triangles in a circle indicate a:
 - a. bidirectional component.
 - b. variable displacement component.
 - c. fixed displacement component.
 - d. unidirectional component.
10. An operator can check the fluid level in a hydraulic tank by all of the following, *except* a:
 - a. sight glass.
 - b. sensor.
 - c. dipstick.
 - d. scanner.
4. Technician A says a basic hydraulic system includes a pressure relief valve. Technician B says an accumulator is always part of a basic hydraulic system. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
5. Technician A says some MORE uses solar power for their prime mover. Technician B says a diesel engine is the most common prime mover found on MORE. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
6. Technician A says a vented tank uses an external pressure source to keep the tank pressurized. Technician B says a pressurized tank is used to help ensure a good supply of oil to the pumps inlet. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
7. Technician A says vane pumps have two main rotating components (rotor and vanes). Technician B says a piston pump's displacement is determined by its swashplate angle. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B

ASE Technician A/Technician B Style Questions

1. Technician A says an open-loop hydraulic system has its pump output flow directly to a motor. Technician B says a closed-loop hydraulic system needs the pump inlet to be connected to the reservoir. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
2. Technician A says an open center hydraulic system is usually paired with a fixed displacement pump. Technician B says a closed center hydraulic system is usually paired with a variable displacement pump. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
3. Technician A says a hydraulic cylinder is sometimes called a rotary actuator. Technician B says a rotary actuator provides torque output when oil is delivered to it. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
8. Technician A says a properly sized hydraulic conductor will not provide laminar flow. Technician B says it is acceptable to undersize hoses and lines when replacing them. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
9. Technician A says to calculate hydraulic horsepower, you need to know what type of pump is used. Technician B says to calculate cycle time, you need to know the setting of the main relief valve. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B
10. Technician A says the graphic symbol for pumps and motors starts with a square box. Technician B says that linear actuator symbols are based on a circle shape. Who is correct?
 - a. Technician A
 - b. Technician B
 - c. Both A and B
 - d. Neither A nor B

CHAPTER 24

Hydraulic Reservoirs

Knowledge Objectives

After reading this chapter, you will be able to:

- **K24001** Explain the purpose and fundamentals of hydraulic reservoirs.
- **K24002** Describe the types and construction features of hydraulic reservoirs.
- **K24003** Describe the principles of operation of hydraulic reservoirs.

Skills Objectives

After reading this chapter, you will be able to:

- **S24001** Identify the types and construction features of hydraulic reservoirs.
- **S24002** Inspect hydraulic reservoirs, following manufacturers' recommended procedures.
- **S24003** Perform a reservoir drain and cleanout procedure, following manufacturers' recommendations for hydraulic reservoirs.

► Introduction

A hydraulic reservoir has a simple function and doesn't get much attention in terms of service or repair. However, there are some important points to understand about reservoirs.

A hydraulic reservoir is a tank used to store the system fluid. It holds a specific amount of hydraulic fluid to accommodate volume changes in the system and performs a variety of other not-so-obvious important functions. This chapter describes the construction features and functions of hydraulic reservoirs and identifies the types of reservoirs and their uses. It goes on to describe the external and internal components of a properly designed reservoir and explains its functions. The chapter concludes with describing procedures to inspect, drain, clean out, and refill hydraulic reservoirs.

► Purpose and Fundamentals of Hydraulic Reservoirs

K24001

All hydraulic systems found on MORE machines have a reservoir. A technician won't spend a lot of time working on them, but there are a few important points to keep in mind when it comes time for a service or during some diagnostic procedures.

Hydraulic Reservoir Functions

The functions of a hydraulic reservoir consist of one or more of the following: holding an adequate supply of hydraulic fluid and conditioning the fluid (including heating, cooling, dehydration, deaeration, and separating of contaminants from the fluid). Each of these functions is described in detail in this section. **FIGURE 24-1** illustrates a typical hydraulic reservoir on MORE.

The reservoir's primary function is to provide a constant supply of hydraulic fluid for the system's pump(s) and components. The reservoir holds excess hydraulic fluid to accommodate volume changes from cylinder extension and contraction, temperature-driven expansion and contraction, and minor leaks. The reservoir can also function as a simple oil cooler to dissipate waste heat.

The reservoir is also designed to aid in conditioning by removing contaminants. One contaminant—water—can have

FIGURE 24-1 Typical hydraulic reservoir.
